MANDATORY LAW SHALL BE UNAFFECTED BY THE FOREGOING PARAGRAPHS.

INTELLECTUAL PROPERTY OWNERS/COPYRIGHT OWNERS/CONTRIBUTORS: ROBERT BOSCH GMBH, ROBERT BOSCH PLATZ 1, 70839 GERLINGEN, GERMANY AND ITS LICENSORS.

## SPECIFICATION REVISION HISTORY

REVISION	DATE	NOTES
0.1	18.01.2008	initial working revision
0.2	12.02.2008	first revised working revision
0.3	10.03.2008	second revised working revision
0.4	18.04.2008	third revised working revision
0.5	22.07.2008	fourth revised working revision
0.6	24.10.2008	fifth revised working revision
0.7	18.12.2008	sixth revised working revision
1.0	25.03.2009	first complete revision
1.1	25.06.2009	Tx Handler functionality updated
1.2	20.08.2009	register TXBSC removed, RAM Watchdog added
1.21	10.02.2010	address 0x08 reserved for customer defined register
1.22	26.11.2010	minor textual enhancements
1.23	18.02.2011	typos corrected
2.0	27.10.2011	debug on CAN, dedicated Rx Buffers, CAN FD, Extension IF
2.0.1	12.03.2012	minor corrections, interface signals to Clock Calibration on CAN unit updated
2.0.2	23.05.2012	Section 3.1.3 CAN FD Operation corrected
3.0	17.10.2012	FIFO overwrite mode, transmit pause, support of CAN FD 64-byte frames
3.0.1	26.11.2012	registers FBTP and TEST updated, minor textual enhancements
3.0.2	14.02.2013	Section 2.4.1 Message RAM Configuration corrected, minor corrections/enhancements

REVISION	DATE	NOTES
3.1.0	22.07.2014	<p>Register FBTP renamed to DBTP and restructured</p> <ul style="list-style-type: none"> <li>• <b>TDCO</b> moved to new register TDCR</li> <li>• increased configuration range for data bit timing</li> </ul> <p>Register TEST restructured</p> <ul style="list-style-type: none"> <li>• <b>TDCV</b> moved to register PSR</li> </ul> <p>Register CCCR restructured</p> <ul style="list-style-type: none"> <li>• FDBS and FDO removed</li> <li>• new control bit <b>EFBI</b> replaces status flag <b>FDBS</b></li> <li>• new control bit <b>PXHD</b> replaces status flag <b>FDO</b></li> <li>• <b>CMR</b> removed, transmit format configured in Tx Buffer element</li> <li>• <b>CME</b> replaced by <b>FDOE</b> and <b>BRSE</b></li> </ul> <p>Register BTP renamed to NBTP and restructured</p> <ul style="list-style-type: none"> <li>• <b>BRP</b> renamed to <b>NBRP</b>, range reduced</li> <li>• <b>TSEG1</b> renamed to <b>NTSEG1</b>, range expanded</li> <li>• <b>TSEG2</b> renamed to <b>NTSEG2</b>, range expanded</li> <li>• <b>SJW</b> renamed to <b>NSJW</b>, range expanded</li> </ul> <p>Register PSR updated</p> <ul style="list-style-type: none"> <li>• <b>TDCV</b> moved from register TEST, range increased</li> <li>• status flag <b>PXE</b> added</li> <li>• <b>FLEC</b> renamed to <b>DLEC</b></li> </ul> <p>Register TDCR added</p> <ul style="list-style-type: none"> <li>• <b>TDCO</b> moved from register DBTP, range expanded</li> <li>• new configuration <b>TDCF</b> field</li> </ul> <p>Register IR updated</p> <ul style="list-style-type: none"> <li>• interrupt flags <b>STE</b>, <b>FOE</b>, <b>ACKE</b>, <b>BE</b>, <b>CRCE</b> replaced by <b>ARA</b>, <b>PED</b>, <b>PEA</b></li> </ul> <p>Register IE updated</p> <ul style="list-style-type: none"> <li>• interrupt enable bits <b>STEE</b>, <b>FOEE</b>, <b>ACKEE</b>, <b>BEE</b>, <b>CRCEE</b> replaced by <b>ARAE</b>, <b>PEDE</b>, <b>PEAE</b></li> </ul> <p>Register ILS updated</p> <ul style="list-style-type: none"> <li>• interrupt line select bits <b>STEL</b>, <b>FOEL</b>, <b>ACKEL</b>, <b>BEL</b>, <b>CRCEL</b> replaced by <b>ARAL</b>, <b>PEDL</b>, <b>PEAL</b></li> </ul> <p>Rx buffer and FIFO element updated</p> <ul style="list-style-type: none"> <li>• bit <b>EDL</b> renamed to <b>FDF</b></li> </ul> <p>Tx buffer element updated</p> <ul style="list-style-type: none"> <li>• transmission of bit <b>ESI</b> recessive configurable</li> <li>• selection of Classic/FD format transmission via flag <b>FDF</b></li> <li>• configuration of bit rate switching via <b>BRS</b></li> </ul> <p>Section 3.1.3 CAN FD Operation updated</p> <p>Section 3.1.4 Transmitter Delay Compensation updated</p> <p>Minor amendments and textual enhancements</p>
3.1.5	14.10.2014	Bit <b>NISO</b> added to register CCCR
3.2.0	07.11.2014	<p>Table 61: description of m_can_dis_mord updated</p> <p>Baud Rate replaced by Bit Rate</p> <p>Note about Message RAM initialization added</p>
3.2.1	16.03.2015	minor textual enhancements and corrections
3.2.1.1	24.03.2016	References to ISO 11898-1 updated, range of <b>NBTP.NTSEG2</b> updated to fix erratum #16.
3.2.1.2	20.02.2017	Description of <b>DBTP.DBRP</b> in Section 2.3.4 enhanced.

<b>REVISION</b>	<b>DATE</b>	<b>NOTES</b>
3.3.0	30.10.2018	Wide Message Markers, interface to DMU and TSU, and filtering for Sync messages added.
3.3.1	11.03.2023	Range limitation of DTSEG 2 in 2.3.4 harmonized with ISO 11898-1:2015. Wording of the Tx Buffer handling description updated in 3.5.2 and 3.5.4.

**TRACKING OF MAJOR CHANGES**

## TERMS AND ABBREVIATIONS

This document uses the following terms and abbreviations.

Term	Meaning
BRP	Bit Rate Prescaler
BSP	Bit Stream Processor
BTL	Bit Timing Logic
CAN	Controller Area Network
CAN FD	Controller Area Network with Flexible Data-rate
CRC	Cyclic Redundancy Check
DLC	Data Length Code
ECC	Error Correction Code
ECU	Electronic Control Unit
EML	Error Management Logic
EOF	End of Frame
FSM	Finite State Machine
mtq	minimum time quantum = CAN clock period ( <b>m_can_cclk</b> )
SOF	Start of Frame
SSP	Secondary Sample Point
TDC	Transmitter Delay Compensation
tq	time quantum
TSEG1	Time Segment before Sample Point
TSEG2	Time Segment after Sample Point
TTCAN	Time-Triggered CAN

## CONVENTIONS

The following conventions are used within this User's Manual.

<b>Arial bold</b>	Names of bits and ports
<i>Arial italic</i>	States of bits and ports

# Chapter 1.

## 1. Overview

The M\_CAN module is the new CAN Communication Controller IP-module that can be integrated as stand-alone device or as part of an ASIC. It is described in VHDL on RTL level, prepared for synthesis. The M\_CAN performs communication according to ISO 11898-1:2015. Additional transceiver hardware is required for connection to the physical layer.

The message storage is intended to be a single- or dual-ported Message RAM outside of the module. It is connected to the M\_CAN via the Generic Master Interface. Depending on the chosen ASIC integration, multiple M\_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN Core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN Core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M\_CAN can be connected to a wide range of Host CPUs via its 8/16/32-bit Generic Slave Interface. The M\_CAN's clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FM-PLL.

### 1.1 Features

- Conform with ISO 11898-1:2015
- CAN FD with up to 64 data bytes supported
- CAN Error Logging
- AUTOSAR support
- SAE J1939 support
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signalling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M\_CANs may share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8/16/32 bit Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug on CAN support
- DMA Support (DMU add-on required)

- Support of Hardware Timestamping according to CiA 603 (TSU add-on required)

## 1.2 Block Diagram

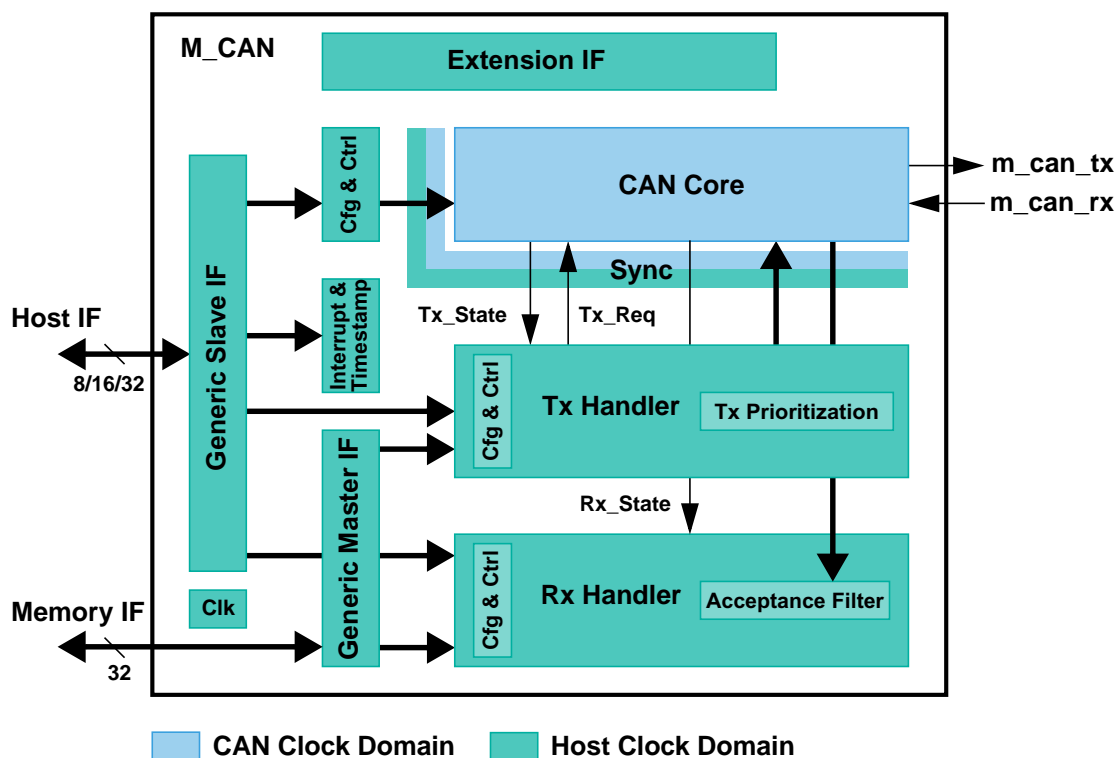

Figure 1 M\_CAN Block Diagram

### CAN Core

CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1:2015 protocol functions. Supports 11-bit and 29-bit identifiers.

### Sync

Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.

### Clk

Synchronizes reset signal to the Host clock domain and to the CAN clock domain.

### Cfg & Ctrl

CAN Core related configuration and control bits.

### Interrupt & Timestamp

Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter for receive and transmit timestamp generation.

### Tx Handler

Controls the message transfer from the external Message RAM to the CAN Core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.

### Rx Handler

Controls the transfer of received messages from the CAN Core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

### Generic Slave Interface

Connects the M\_CAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8/16/32-bit bus to support a wide range of interconnection structures.

### Generic Master Interface

Connects the M\_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16K • 32 bit. A single M\_CAN can use at most 4.25K • 32 bit.

### Extension Interface

All flags from the Interrupt Register IR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M\_CAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

## 1.3 Dual Clock Sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain **m\_can\_hclk**. Due to the high precision clocking requirements of the CAN Core, a separate clock without any modulation has to be provided as **m\_can\_cclk**.

Within the M\_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

**Note:** *In order to achieve a stable function of the M\_CAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of a spread spectrum clock has to be regarded.*

## 1.4 Dual Interrupt Lines

The module provides two interrupt lines. Interrupts can be routed either to **m\_can\_int0** or to **m\_can\_int1**. By default all interrupts are routed to interrupt line **m\_can\_int0**. By programming **ILE.EINT0** and **ILE.EINT1** the interrupt lines can be enabled or disabled separately.

# Chapter 2.

## 2. Programmer's Model

### 2.1 Hardware Reset Description

After hardware reset, the registers of the M\_CAN hold the reset values listed in Table 1. Additionally the *Bus\_Off* state is reset and the output **m\_can\_tx** is set to *recessive* (HIGH). The value 0x0001 (**CCCR.INIT** = '1') in the CC Control Register enables software initialization. The M\_CAN does not influence the CAN bus until the CPU resets **CCCR.INIT** to '0'.

### 2.2 Register Map

The M\_CAN module allocates an address space of 512 bytes. All registers are organized as 32-bit registers. The M\_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8 bit (byte access), 16 bit (half-word access), or 32 bit (word access). Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only with **CCCR.CCE**='1' AND **CCCR.INIT**='1'. There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

R = Read, S = Set on read, X = Reset on read, W = Write, P = Protected write, p = Protected set, C = Clear/preset on write, r = release, d = date

Table 1 M\_CAN Register Map

### 2.2.1 Access to reserved Register Addresses

In case the application software wants to access one of the reserved addresses in the M\_CAN register map (read or write access), interrupt flag **IR.ARA** is set, and if enable the interrupt is signalled via the assigned interrupt line (**m\_can\_int0** or **m\_can\_int1**). If the CPU interface allows byte or half-word accesses, this interrupt flag is only set for accesses to reserved addresses where all four bytes are reserved. In case one of the optional add-on modules DMU and/or TSU is connected to the M\_CAN, this flag is also set when a reserved address of such a module is accessed.

In addition accesses to reserved addresses are directly signalled to the Host CPU by activating output signal **m\_can\_aei\_ara** when accessing a reserved address.

## 2.3 Registers

### 2.3.1 Customer Register

Address 0x08 is reserved for an optional 32 bit customer-specific register. The Customer Register is intended to hold customer-specific configuration, control, and status bits. A description of the functionality is not part of this document.

### 2.3.2 Core Release Register (CREL)

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x00	REL[3:0]				STEP[3:0]				SUBSTEP[3:0]				YEAR[3:0]			
	R-r				R-r				R-r				R-d			
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MON[7:0]								DAY[7:0]							
	R-d								R-d							

R = Read; -r = release, -d = time stamp, value defined at synthesis by generic parameter

Table 2 Core Release Register (addresses 0x00)

**Bits 31:28 REL[3:0]:** Core Release

One digit, BCD-coded.

**Bits 27:24 STEP[3:0]:** Step of Core Release

One digit, BCD-coded.

**Bits 23:20 SUBSTEP[3:0]:** Sub-step of Core Release

One digit, BCD-coded.

**Bits 19:16 YEAR[3:0]:** Time Stamp Year

One digit, BCD-coded. This field is set by generic parameter on M\_CAN synthesis.

**Bits 15:8 MON[7:0]:** Time Stamp Month

Two digits, BCD-coded. This field is set by generic parameter on M\_CAN synthesis.

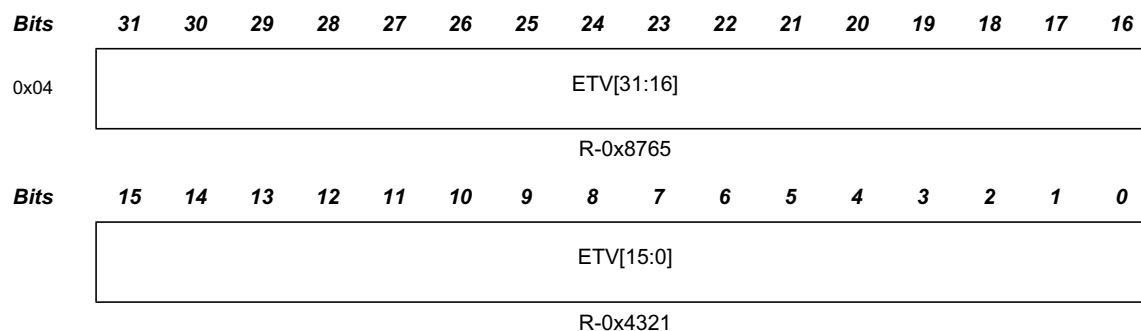

**Bits 7:0 DAY[7:0]:** Time Stamp Day

Two digits, BCD-coded. This field is set by generic parameter on M\_CAN synthesis.

Release	Step	SubStep	Year	Month	Day	Name
0	2	0	9	03	26	Revision 0.2.0, Date 2009/03/26

Table 3 Example for Coding of Revisions

### 2.3.3 Endian Register (ENDN)

R = Read; -t = test value

Table 4 Endian Register (address 0x04)

**Bits 31:0 ETV[31:0]:** Endianness Test Value

The endianness test value is 0x87654321.

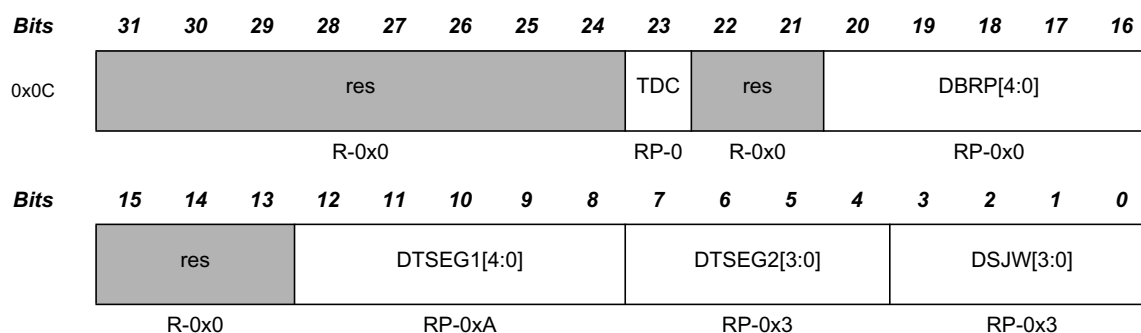

### 2.3.4 Data Bit Timing & Prescaler Register (DBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 **m\_can\_cclk** periods.  $t_q = (\text{DBRP} + 1) \text{mtq}$ .

**DTSEG1** is the sum of Prop\_Seg and Phase\_Seg1. **DTSEG2** is Phase\_Seg2.

Therefore the length of the bit time is (programmed values) **[DTSEG1 + DTSEG2 + 3]  $t_q$**   
or (functional values) **[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2]  $t_q$** .

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

R = Read, P = Protected write; -n = value after reset

Table 5 Data Bit Timing & Prescaler Register (address 0x0C)

**Bit 23 TDC:** Transmitter Delay Compensation

0= Transmitter Delay Compensation disabled

1= Transmitter Delay Compensation enabled

**Bits 20:16 DBRP[4:0]:** Data Bit Rate Prescaler

0x00-0x1F The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Bit Rate Prescaler are 0 to 31. When **TDC** = '1', the range is limited to 0,1. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

**Bits 12:8 DTSEG1[4:0]:** Data time segment before sample point

0x00-0x1F Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

**Bits 7:4 DTSEG2[3:0]:** Data time segment after sample point

0x1-0xF Valid values are 1 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

**Bits 3:0 DSJW[3:0]:** Data (Re)Synchronization Jump Width

0x0-0xF Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

**Note:** With a CAN clock (*m\_can\_cclk*) of 8 MHz, the reset value of 0x00000A33 configures the M\_CAN for a data phase bit rate of 500 kBit/s.

**Note:** The bit rate configured for the CAN FD data phase via DBTP must be higher or equal to the bit rate configured for the arbitration phase via NBTP.

### 2.3.5 Test Register (TEST)

Write access to the Test Register has to be enabled by setting bit **CCCR.TEST** to '1'. All Test Register functions are set to their reset values when bit **CCCR.TEST** is reset.

Loop Back Mode and software control of pin *m\_can\_tx* are hardware test modes. Programming of **TX** ≠ "00" may disturb the message transfer on the CAN bus.

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x10	res										SVAL	TXBNS[4:0]				
	R-0x0										R-0	R-0x0				
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	res		PVAL	TXBNP[4:0]				RX	TX[1:0]		LBCK	res				
	R-0x0		R-0	R-0x0				R-U	RP-0x0		RP-0	R-0x0				

R = Read, P = Protected write, -U = undefined; -n = value after reset

Table 6 Test Register (address 0x10)

**Bit 21 SVAL:** Started Valid

0= Value of **TXBNS** not valid

1= Value of **TXBNS** valid

**Bits 20:16 TXBNS[4:0]:** Tx Buffer Number Started

0x00-0x1F Tx Buffer number of message whose transmission was started last. Valid when **SVAL** is set. Valid values are 0 to 31.

**Bit 13 PVAL:** Prepared Valid

0= Value of **TXBNP** not valid

1= Value of **TXBNP** valid

**Bits 12:8 TXBNP[4:0]:** Tx Buffer Number Prepared

0x00-0x1F Tx Buffer number of message that is ready for transmission. Valid when **PVAL** is set. Valid values are 0 to 31.

**Bit 7      RX:**      Receive Pin

Monitors the actual value of pin **m\_can\_rx**

0= The CAN bus is dominant (**m\_can\_rx** = '0')

1= The CAN bus is recessive (**m\_can\_rx** = '1')

**Bits 6:5      TX[1:0]:**      Control of Transmit Pin

00 Reset value, **m\_can\_tx** controlled by the CAN Core, updated at the end of the CAN bit time

01 Sample Point can be monitored at pin **m\_can\_tx**

10 Dominant ('0') level at pin **m\_can\_tx**

11 Recessive ('1') at pin **m\_can\_tx**

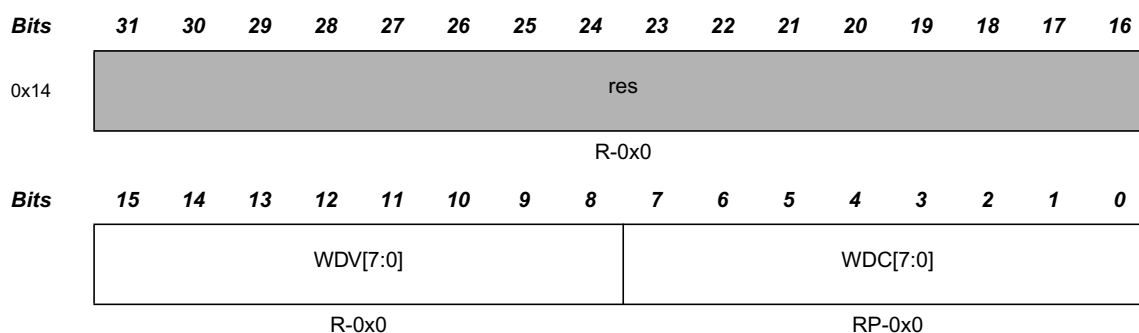

**Bit 4      LBCK:**      Loop Back Mode

0= Reset value, Loop Back Mode is disabled

1= Loop Back Mode is enabled (see Chapter 3.1.9)

**2.3.6      RAM Watchdog (RWD)**

The RAM Watchdog monitors the READY output of the Message RAM (**m\_can\_aeim\_ready**). A Message RAM access via the M\_CAN's Generic Master Interface (**m\_can\_aeim\_sel** active) starts the Message RAM Watchdog Counter with the value configured by **RWD.WDC**. The counter is reloaded with **RWD.WDC** when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag **IR.WDI** is set. The RAM Watchdog Counter is clocked by the Host clock (**m\_can\_hclk**).

R = Read, W = Write, P = Protected write; -n = value after reset

**Table 7      RAM Watchdog (address 0x14)**

**Bits 7:0      WDV[7:0]:**      Watchdog Value

Actual Message RAM Watchdog Counter Value.

**Bits 7:0      WDC[7:0]:**      Watchdog Configuration

Start value of the Message RAM Watchdog Counter. With the reset value of "00" the counter is disabled.

### 2.3.7 CC Control Register (CCCR)

For details about setting and resetting of single bits see Section 3.1.1.

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x18	res															
	R-0x0															
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NISO	TXP	EFBI	PXHD	WMM	UTSU	BRSE	FDOE	TEST	DAR	MON	CSR	CSA	ASM	CCE	INIT
	RP-0	RP-0	RP-0	RP-0	RP-0	RP-0	RP-0	RP-0	Rp-0	RP-0	Rp-0	RW-0	R-0	Rp-0	RP-0	RW-1

R = Read, W = Write, P = Protected write, p = Protected set; -n = value after reset

Table 8 CC Control Register (address 0x18)

**Bit 15 NISO:** Non ISO Operation

If this bit is set, the M\_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0.

0= CAN FD frame format according to ISO 11898-1:2015

1= CAN FD frame format according to Bosch CAN FD Specification V1.0

**Note:** When the generic parameter *iso\_only\_g* is set to '1' in hardware synthesis, this bit becomes reserved and is read as '0'. The M\_CAN always operates with the CAN FD frame format according to ISO 11898-1:2015.

**Bit 14 TXP:** Transmit Pause

If this bit is set, the M\_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame (see Section 3.5).

0= Transmit pause disabled

1= Transmit pause enabled

**Bit 13 EFBI:** Edge Filtering during Bus Integration

0= Edge filtering disabled

1= Two consecutive dominant tq required to detect an edge for hard synchronization

**Bit 12 PXHD:** Protocol Exception Handling Disable

0= Protocol exception handling enabled

1= Protocol exception handling disabled

**Note:** When protocol exception handling is disabled, the M\_CAN will transmit an error frame when it detects a protocol exception condition.

**Bit 11 WMM:** Wide Message Marker

Enables the use of 16-bit Wide Message Markers. When 16-bit Wide Message Markers are used (**WMM** = '1'), 16-bit internal timestamping is disabled for the Tx Event FIFO.

0= 8-bit Message Marker used

1= 16-bit Message Marker used, replacing 16-bit timestamps in Tx Event FIFO

**Bit 10 UTSU:** Use Timestamping Unit

When **UTSU** is set, 16-bit Wide Message Markers are also enabled regardless of the value of **WMM**.

0= Internal time stamping

1= External time stamping by TSU

**Note:** When generic parameter `connected_tsu_g` = '0', there is no TSU connected to the M\_CAN. In this case bit `UTSU` is fixed to zero by synthesis.

**Bit 9 BRSE:** Bit Rate Switch Enable

0= Bit rate switching for transmissions disabled

1= Bit rate switching for transmissions enabled

**Note:** When CAN FD operation is disabled `FDOE` = '0', `BRSE` is not evaluated.

**Bit 8 FDOE:** FD Operation Enable

0= FD operation disabled

1= FD operation enabled

**Bit 7 TEST:** Test Mode Enable

0= Normal operation, register **TEST** holds reset values

1= Test Mode, write access to register **TEST** enabled

**Bit 6 DAR:** Disable Automatic Retransmission

0= Automatic retransmission of messages not transmitted successfully enabled

1= Automatic retransmission disabled

**Bit 5 MON** Bus Monitoring Mode

Bit **MON** can only be set by the Host when both **CCE** and **INIT** are set to '1'. The bit can be reset by the Host at any time.

0= Bus Monitoring Mode is disabled

1= Bus Monitoring Mode is enabled

**Bit 4 CSR:** Clock Stop Request

0= No clock stop is requested

1= Clock stop requested. When clock stop is requested, first **INIT** and then **CSA** will be set after all pending transfer requests have been completed and the CAN bus reached *idle*.

**Bit 3 CSA:** Clock Stop Acknowledge

0= No clock stop acknowledged

1= M\_CAN may be set in power down by stopping `m_can_hclk` and `m_can_cclk`

**Bit 2 ASM** Restricted Operation Mode

Bit **ASM** can only be set by the Host when both **CCE** and **INIT** are set to '1'. The bit can be reset by the Host at any time. For a description of the Restricted Operation Mode see Section 3.1.5.

0= Normal CAN operation

1= Restricted Operation Mode active

**Bit 1 CCE:** Configuration Change Enable

0= The CPU has no write access to the protected configuration registers

1= The CPU has write access to the protected configuration registers (while **CCCR.INIT** = '1')

**Bit 0 INIT:** Initialization

0= Normal Operation

1= Initialization is started

**Note:** Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to **INIT** can be read back. Therefore the programmer has to assure that the previous value written to **INIT** has been accepted by reading **INIT** before setting **INIT** to a new value.

### 2.3.8 Nominal Bit Timing & Prescaler Register (NBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 **m\_can\_cclk** periods.  $t_q = (\text{NBRP} + 1) \text{mtq}$ .

**NTSEG1** is the sum of Prop\_Seg and Phase\_Seg1. **NTSEG2** is Phase\_Seg2.

Therefore the length of the bit time is (programmed values) [**NTSEG1** + **NTSEG2** + 3]  $t_q$  or (functional values) [Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2]  $t_q$ .

The Information Processing Time (IPT) is *zero*, meaning the data for the next bit is available at the first clock edge after the sample point.

R = Read, P = Protected write; -n = value after reset

Table 9 Nominal Bit Timing & Prescaler Register (address 0x1C)

**Bits 31:25 NSJW[6:0]:** Nominal (Re)Synchronization Jump Width

0x00-0x7F Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

**Bits 24:16 NBRP[8:0]:** Nominal Bit Rate Prescaler

0x000-0x1FF The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Bit Rate Prescaler are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

**Bits 15:8 NTSEG1[7:0]:** Nominal Time segment before sample point

0x01-0xFF Valid values are 1 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

**Bits 6:0 NTSEG2[6:0]:** Nominal Time segment after sample point

0x01-0x7F Valid values are 1 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

**Note:** With a CAN clock (**m\_can\_cclk**) of 8 MHz, the reset value of 0x06000A03 configures the **M\_CAN** for a bit rate of 500 kBit/s.

### 2.3.9 Timestamp Counter Configuration (TSCC)

Configuration of the internal 16-bit Timestamp Counter. The use of the internal Timestamp Counter is enabled by **CCCR.UTSU** = '0'. Handling of internal / external timestamps is described in Section 3.2, *Timestamp Generation*.

R = Read, P = Protected write; -n = value after reset

Table 10 Timestamp Counter Configuration (address 0x20)

**Bit 19:16 TCP[3:0]:** Timestamp Counter Prescaler

0x0-0xF Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1...16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

**Note:** With CAN FD an external counter is required for timestamp generation (TSS = "10")

**Bits 1:0 TSS[1:0]:** Timestamp Select

00= Timestamp counter value always 0x0000

01= Timestamp counter value incremented according to **TCP**

10= External timestamp counter value used

11= Same as "00"

### 2.3.10 Timestamp Counter Value (TSCV)

R = Read, C = Clear on write; -n = Value after reset

Table 11 Timestamp Counter Value (address 0x24)

**Bit 15:0 TSC[15:0]:** Timestamp Counter

The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When **TSCC.TSS** = "01", the Timestamp Counter is incremented in multiples of CAN bit times [1...16] depending on the configuration of **TSCC.TCP**. A wrap around sets interrupt flag **IR.TSW**. Write access resets the counter to zero. When **TSCC.TSS** = "10", **TSC** reflects the external Timestamp Counter value. A write access has no impact.

**Note:** A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

**Note:** Byte access: Writing one of the register bytes 3/2/1/0 will reset the Timestamp Counter.

### 2.3.11 Timeout Counter Configuration (TOCC)

For a description of the Timeout Counter see Section 3.3, *Timeout Counter*.

R = Read, P = Protected write; -n = value after reset

Table 12 Timeout Counter Configuration (address 0x28)

**Bit 31:16 TOP[15:0]:** Timeout Period

Start value of the Timeout Counter (down-counter). Configures the Timeout Period.

**Bits 2:1 TOS[1:0]:** Timeout Select

When operating in Continuous mode, a write to **TOCV** presets the counter to the value configured by **TOCC.TOP** and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by **TOCC.TOP**. Down-counting is started when the first FIFO element is stored.

00= Continuous operation

01= Timeout controlled by Tx Event FIFO

10= Timeout controlled by Rx FIFO 0

11= Timeout controlled by Rx FIFO 1

**Bit 0 ETOC:** Enable Timeout Counter

0= Timeout Counter disabled

1= Timeout Counter enabled

**Note:** For use of timeout function with CAN FD see Section 3.3.

### 2.3.12 Timeout Counter Value (TOCV)

R = Read, C = Clear on write; -n = value after reset

Table 13 Timeout Counter Value (address 0x2C)

**Bit 15:0 TOC[15:0]:** Timeout Counter

The Timeout Counter is decremented in multiples of CAN bit times [1...16] depending on the configuration of **TSCC.TCP**. When decremented to zero, interrupt flag **IR.TOO** is set and the Timeout Counter is stopped. Start and reset/restart conditions are configured via **TOCC.TOS**.

**Note: Byte access: when TOCC.TOS = "00" writing one of the register bytes 3/2/1/0 will preset the Timeout Counter.**

### 2.3.13 Error Counter Register (ECR)

R = Read, X = Reset on read; -n = value after reset

**Table 14** Error Counter Register (address 0x40)

#### Bits 23:16 CEL[7:0]: CAN Error Logging

The counter is incremented each time when a CAN protocol error causes the 8-bit Transmit Error Counter **TEC** or the 7-bit Receive Error Counter **REC** to be incremented. The counter is also incremented when the Bus\_Off limit is reached. It is not incremented when only **RP** is set without changing **REC**. The increment of **CEL** follows after the increment of **REC** or **TEC**.

The counter is reset by read access to **CEL**. The counter stops at 0xFF; the next increment of **TEC** or **REC** sets interrupt flag **IR.ELO**.

**Note: Byte access: Reading byte 2 will reset CEL to zero, reading bytes 3/1/0 has no impact.**

#### Bit 15 RP: Receive Error Passive

0= The Receive Error Counter is below the *error passive* level of 128

1= The Receive Error Counter has reached the *error passive* level of 128

#### Bits 14:8 REC[6:0]: Receive Error Counter

Actual state of the Receive Error Counter, values between 0 and 127

#### Bits 7:0 TEC[7:0]: Transmit Error Counter

Actual state of the Transmit Error Counter, values between 0 and 255

**Note: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.**

### 2.3.14 Protocol Status Register (PSR)

R = Read, S = Set on read, X = Reset on read; -n = value after reset

Table 15 Protocol Status Register (address 0x44)

**Bits 22:16 TDCV[6:0]:** Transmitter Delay Compensation Value

0x00-0x7F Position of the secondary sample point, defined by the sum of the measured delay from **m\_can\_tx** to **m\_can\_rx** and **TDCR.TDCO**. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.

**Bit 14 PXE:** Protocol Exception Event

- 0= No protocol exception event occurred since last read access
- 1= Protocol exception event occurred

**Note: Byte access: Reading byte 0 will reset PXE, reading bytes 3/2/1 has no impact.**

**Bit 13 RFDF:** Received a CAN FD Message

This bit is set independent of acceptance filtering.

- 0= Since this bit was reset by the CPU, no CAN FD message has been received
- 1= Message in CAN FD format with **FDF** flag set has been received

**Note: Byte access: Reading byte 0 will reset RFDF, reading bytes 3/2/1 has no impact.**

**Bit 12 RBR:** BRS flag of last received CAN FD Message

This bit is set together with **RFDF**, independent of acceptance filtering.

- 0= Last received CAN FD message did not have its **BRS** flag set
- 1= Last received CAN FD message had its **BRS** flag set

**Note: Byte access: Reading byte 0 will reset RBR, reading bytes 3/2/1 has no impact.**

**Bit 11 RESI:** ESI flag of last received CAN FD Message

This bit is set together with **RFDF**, independent of acceptance filtering.

- 0= Last received CAN FD message did not have its **ESI** flag set
- 1= Last received CAN FD message had its **ESI** flag set

**Note: Byte access: Reading byte 0 will reset RESI, reading bytes 3/2/1 has no impact.**

**Bits 10:8 DLEC[2:0]:** Data Phase Last Error Code

Type of last error that occurred in the data phase of a CAN FD format frame with its **BRS** flag set. Coding is the same as for **LEC**. This field will be cleared to zero when a CAN FD format frame with its **BRS** flag set has been transferred (reception or transmission) without error.

**Note: Byte access: Reading byte 0 will set DLEC to "111", reading bytes 3/2/1 has no impact.**

**Bit 7 BO:** Bus\_Off Status

- 0= The M\_CAN is not Bus\_Off
- 1= The M\_CAN is in Bus\_Off state

**Bit 6 EW:** Warning Status

- 0= Both error counters are below the Error\_Warning limit of 96
- 1= At least one of error counter has reached the Error\_Warning limit of 96

**Bit 5 EP:** Error Passive

- 0= The M\_CAN is in the Error\_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected
- 1= The M\_CAN is in the Error\_Passive state

**Bits 4:3 ACT[1:0]:** Activity

Monitors the module's CAN communication state.

- 00= Synchronizing - node is synchronizing on CAN communication
- 01= Idle - node is neither receiver nor transmitter
- 10= Receiver - node is operating as receiver
- 11= Transmitter - node is operating as transmitter

**Note:** *ACT is set to "00" by a Protocol Exception Event.*

**Bits 2:0 LEC[2:0]:** Last Error Code

The **LEC** indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.

- 0= **No Error:** No error occurred since **LEC** has been reset by successful reception or transmission.
- 1= **Stuff Error:** More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
- 2= **Form Error:** A fixed format part of a received frame has the wrong format.
- 3= **AckError:** The message transmitted by the M\_CAN was not acknowledged by another node.
- 4= **Bit1Error:** During the transmission of a message (with the exception of the arbitration field), the device wanted to send a *recessive* level (bit of logical value '1'), but the monitored bus value was *dominant*.
- 5= **Bit0Error:** During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a *dominant* level (data or identifier bit logical value '0'), but the monitored bus value was *recessive*. During *Bus\_Off* recovery this status is set each time a sequence of 11 *recessive* bits has been monitored. This enables the CPU to monitor the proceeding of the *Bus\_Off* recovery sequence (indicating the bus is not stuck at *dominant* or continuously disturbed).
- 6= **CRCError:** The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.
- 7= **NoChange:** Any read access to the Protocol Status Register re-initializes the **LEC** to '7'. When the **LEC** shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

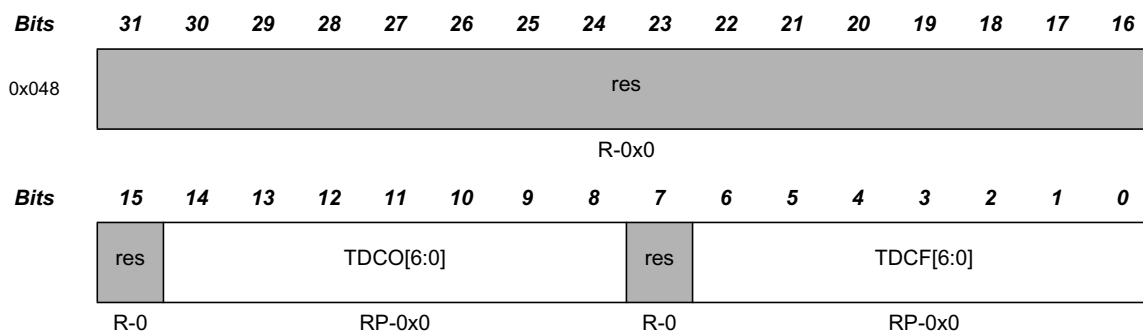

**Note:** *When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.*

**Note:** *The Bus\_Off recovery sequence (see ISO 11898-1:2015) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus\_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 \* 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus\_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus*

*is stuck at dominant or continuously disturbed and to monitor the Bus\_Off recovery sequence. ECR.REC is used to count these sequences.*

**Note:** Byte access: Reading byte 0 will set LEC to “111”, reading bytes 3/2/1 has no impact.

### 2.3.15 Transmitter Delay Compensation Register (TDCR)

R = Read, P = Protected write; -n = value after reset

**Table 16** Transmitter Delay Compensation Register (address 0x048)

**Bits 14:8 TDCO[6:0]:** Transmitter Delay Compensation SSP Offset

0x00-0x7F Offset value defining the distance between the measured delay from **m\_can\_tx** to **m\_can\_rx** and the secondary sample point. Valid values are 0 to 127 mtq.

**Bits 6:0 TDCF[6:0]:** Transmitter Delay Compensation Filter Window Length

0x00-0x7F Defines the minimum value for the SSP position, dominant edges on **m\_can\_rx** that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when **TDCF** is configured to a value greater than **TDCO**. Valid values are 0 to 127 mtq.

### 2.3.16 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of **IE** controls whether an interrupt is generated. The configuration of **ILS** controls on which interrupt line an interrupt is signalled.

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R = Read, W = Write; -n = value after reset

Table 17 Interrupt Register (address 0x50)

- Bit 29 ARA:** Access to Reserved Address  
 0= No access to reserved address occurred  
 1= Access to reserved address occurred
- Bit 28 PED:** Protocol Error in Data Phase (Data Bit Time is used)  
 0= No protocol error in data phase  
 1= Protocol error in data phase detected (**PSR.DLEC** ≠ 0,7)
- Bit 27 PEA:** Protocol Error in Arbitration Phase (Nominal Bit Time is used)  
 0= No protocol error in arbitration phase  
 1= Protocol error in arbitration phase detected (**PSR.LEC** ≠ 0,7)
- Bit 26 WDI:** Watchdog Interrupt  
 0= No Message RAM Watchdog event occurred  
 1= Message RAM Watchdog event due to missing READY
- Bit 25 BO:** Bus\_Off Status  
 0= Bus\_Off status unchanged  
 1= Bus\_Off status changed
- Bit 24 EW:** Warning Status  
 0= Error\_Warning status unchanged  
 1= Error\_Warning status changed
- Bit 23 EP:** Error Passive  
 0= Error\_Passive status unchanged  
 1= Error\_Passive status changed
- Bit 22 ELO:** Error Logging Overflow  
 0= CAN Error Logging Counter did not overflow  
 1= Overflow of CAN Error Logging Counter occurred

**Bit 21 BEU:** Bit Error Uncorrected

Message RAM bit error detected, uncorrected. Controlled by input signal **m\_can\_aeim\_berr[1]** generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets **CCCR.INIT** to '1'. This is done to avoid transmission of corrupted data.

- 0= No bit error detected when reading from Message RAM  
 1= Bit error detected, uncorrected (e.g. parity logic)

**Bit 20 BEC:** Bit Error Corrected

Message RAM bit error detected and corrected. Controlled by input signal **m\_can\_aeim\_berr[0]** generated by an optional external parity / ECC logic attached to the Message RAM.

- 0= No bit error detected when reading from Message RAM  
 1= Bit error detected and corrected (e.g. ECC)

**Bit 19 DRX:** Message stored to Dedicated Rx Buffer

The flag is set whenever a received message has been stored into a dedicated Rx Buffer.

- 0= No Rx Buffer updated  
 1= At least one received message stored into an Rx Buffer

**Bit 18 TOO:** Timeout Occurred

- 0= No timeout  
 1= Timeout reached

**Bit 17 MRAF:** Message RAM Access Failure

The flag is set, when the Rx Handler

- has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message.
- was not able to write a message to the Message RAM. In this case message storage is aborted.

In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location.

The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the M\_CAN is switched into Restricted Operation Mode (see Section 3.1.5). To leave Restricted Operation Mode, the Host CPU has to reset **CCCR.ASM**.

- 0= No Message RAM access failure occurred  
 1= Message RAM access failure occurred

**Bit 16 TSW:** Timestamp Wraparound

- 0= No timestamp counter wrap-around  
 1= Timestamp counter wrapped around

**Bit 15 TEFL:** Tx Event FIFO Element Lost

- 0= No Tx Event FIFO element lost  
 1= Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero

**Bit 14 TEFF:** Tx Event FIFO Full

- 0= Tx Event FIFO not full  
 1= Tx Event FIFO full

**Bit 13 TEFW:** Tx Event FIFO Watermark Reached

- 0= Tx Event FIFO fill level below watermark  
 1= Tx Event FIFO fill level reached watermark

- Bit 12**      **TEFN:**    Tx Event FIFO New Entry  
0= Tx Event FIFO unchanged  
1= Tx Handler wrote Tx Event FIFO element
- Bit 11**      **TFE:**      Tx FIFO Empty  
0= Tx FIFO non-empty  
1= Tx FIFO empty
- Bit 10**      **TCF:**      Transmission Cancellation Finished  
0= No transmission cancellation finished  
1= Transmission cancellation finished
- Bit 9**        **TC:**        Transmission Completed  
0= No transmission completed  
1= Transmission completed
- Bit 8**        **HPM:**      High Priority Message  
0= No high priority message received  
1= High priority message received
- Bit 7**        **RF1L:**      Rx FIFO 1 Message Lost  
0= No Rx FIFO 1 message lost  
1= Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero
- Bit 6**        **RF1F:**      Rx FIFO 1 Full  
0= Rx FIFO 1 not full  
1= Rx FIFO 1 full
- Bit 5**        **RF1W:**      Rx FIFO 1 Watermark Reached  
0= Rx FIFO 1 fill level below watermark  
1= Rx FIFO 1 fill level reached watermark
- Bit 4**        **RF1N:**      Rx FIFO 1 New Message  
0= No new message written to Rx FIFO 1  
1= New message written to Rx FIFO 1
- Bit 3**        **RF0L:**      Rx FIFO 0 Message Lost  
0= No Rx FIFO 0 message lost  
1= Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero
- Bit 2**        **RF0F:**      Rx FIFO 0 Full  
0= Rx FIFO 0 not full  
1= Rx FIFO 0 full
- Bit 1**        **RF0W:**      Rx FIFO 0 Watermark Reached  
0= Rx FIFO 0 fill level below watermark  
1= Rx FIFO 0 fill level reached watermark
- Bit 0**        **RF0N:**      Rx FIFO 0 New Message  
0= No new message written to Rx FIFO 0  
1= New message written to Rx FIFO 0

### 2.3.17 Interrupt Enable (IE)

The settings in the Interrupt Enable register determine which status changes in the Interrupt Register will be signalled on an interrupt line.

0= Interrupt disabled

1= Interrupt enabled

### 2.3.18 Interrupt Line Select (ILS)

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via **ILE.EINT0** and **ILE.EINT1**.

0= Interrupt assigned to interrupt line **m\_can\_int0**

1= Interrupt assigned to interrupt line **m\_can\_int1**

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 2.3.19 Interrupt Line Enable (ILE)

Each of the two interrupt lines to the CPU can be enabled / disabled separately by programming bits **EINT0** and **EINT1**.

R = Read, W = Write; -n = value after reset

**Table 20** Interrupt Line Select (address 0x5C)

<b>Bit 1</b>	<b>EINT1:</b>	Enable Interrupt Line 1
0=	Interrupt line <b>m_can_int1</b> disabled	
1=	Interrupt line <b>m_can_int1</b> enabled	
<b>Bit 0</b>	<b>EINT0:</b>	Enable Interrupt Line 0
0=	Interrupt line <b>m_can_int0</b> disabled	
1=	Interrupt line <b>m_can_int0</b> enabled	

### 2.3.20 Global Filter Configuration (GFC)

Global settings for Message ID filtering. The Global Filter Configuration controls the filter path for standard and extended messages as described in Figure 6 and Figure 7.

R = Read, P = Protected write; -n = value after reset

Table 21 Global Filter Configuration (address 0x80)

#### Bit 5:4 ANFS[1:0]: Accept Non-matching Frames Standard

Defines how received messages with 11-bit IDs that do not match any element of the filter list are treated.

00= Accept in Rx FIFO 0

01= Accept in Rx FIFO 1

10= Reject

11= Reject

#### Bit 3:2 ANFE[1:0]: Accept Non-matching Frames Extended

Defines how received messages with 29-bit IDs that do not match any element of the filter list are treated.

00= Accept in Rx FIFO 0

01= Accept in Rx FIFO 1

10= Reject

11= Reject

#### Bit 1 RRFS: Reject Remote Frames Standard

0= Filter remote frames with 11-bit standard IDs

1= Reject all remote frames with 11-bit standard IDs

#### Bit 0 RRFE: Reject Remote Frames Extended

0= Filter remote frames with 29-bit extended IDs

1= Reject all remote frames with 29-bit extended IDs

### 2.3.21 Standard ID Filter Configuration (SIDFC)

Settings for 11-bit standard Message ID filtering. The Standard ID Filter Configuration controls the filter path for standard messages as described in Figure 6.

R = Read, P = Protected write; -n = value after reset

Table 22 Standard ID Filter Configuration (address 0x84)

**Bit 23:16 LSS[7:0]:** List Size Standard

0= No standard Message ID filter

1-128= Number of standard Message ID filter elements

>128= Values greater than 128 are interpreted as 128

**Bit 15:2 FLSSA[15:2]:** Filter List Standard Start Address

Start address of standard Message ID filter list (32-bit word address, see Figure 2).

### 2.3.22 Extended ID Filter Configuration (XIDFC)

Settings for 29-bit extended Message ID filtering. The Extended ID Filter Configuration controls the filter path for standard messages as described in Figure 7.

R = Read, P = Protected write; -n = value after reset

Table 23 Extended ID Filter Configuration (address 0x88)

**Bit 22:16 LSE[6:0]:** List Size Extended

0= No extended Message ID filter

1-64= Number of extended Message ID filter elements

>64= Values greater than 64 are interpreted as 64

**Bit 15:2 FLESA[15:2]:** Filter List Extended Start Address

Start address of extended Message ID filter list (32-bit word address, see Figure 2).

### 2.3.23 Extended ID AND Mask (XIDAM)

R = Read, P = Protected write; -n = value after reset

Table 24 Extended ID AND Mask (address 0x90)

#### Bit 28:0 EIDM[28:0]: Extended ID Mask

For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active.

### 2.3.24 High Priority Message Status (HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

R = Read; -n = Value after reset

Table 25 High Priority Message Status (address 0x94)

#### Bit 15 FLST: Filter List

Indicates the filter list of the matching filter element.

0= Standard Filter List

1= Extended Filter List

#### Bit 14:8 FIDX[6:0]: Filter Index

Index of matching filter element. Range is 0 to **SIDFC.LSS** - 1 resp. **XIDFC.LSE** - 1.

#### Bit 7:6 MSI[1:0]: Message Storage Indicator

00= No FIFO selected

01= FIFO message lost

10= Message stored in FIFO 0

11= Message stored in FIFO 1

#### Bit 5:0 BIDX[5:0]: Buffer Index

Index of Rx FIFO element to which the message was stored. Only valid when **MSI[1]** = '1'.

### 2.3.25 New Data 1 (NDAT1)

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x98	ND31	ND30	ND29	ND28	ND27	ND26	ND25	ND24	ND23	ND22	ND21	ND20	ND19	ND18	ND17	ND16
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ND15	ND14	ND13	ND12	ND11	ND10	ND9	ND8	ND7	ND6	ND5	ND4	ND3	ND2	ND1	ND0
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = Read; -n = value after reset

Table 26 New Data 1 (address 0x98)

#### Bit 31:0 ND[31:0]: New Data

The register holds the New Data flags of Rx Buffers 0 to 31. The flags are set when the respective Rx Buffer has been updated from a received frame. The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register.

0= Rx Buffer not updated

1= Rx Buffer updated from new message

### 2.3.26 New Data 2 (NDAT2)

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x9C	ND63	ND62	ND61	ND60	ND59	ND58	ND57	ND56	ND55	ND54	ND53	ND52	ND51	ND50	ND49	ND48
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ND47	ND46	ND45	ND44	ND43	ND42	ND41	ND40	ND39	ND38	ND37	ND36	ND35	ND34	ND33	ND32
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = Read; -n = value after reset

Table 27 New Data 2 (address 0x9C)

#### Bit 31:0 ND[63:32]: New Data

The register holds the New Data flags of Rx Buffers 32 to 63. The flags are set when the respective Rx Buffer has been updated from a received frame. The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register.

0= Rx Buffer not updated

1= Rx Buffer updated from new message

**2.3.27 Rx FIFO 0 Configuration (RXF0C)**

R = Read, P = Protected write; -n = Value after reset

**Table 28 Rx FIFO 0 Configuration (address 0xA0)****Bit 31 F0OM:** FIFO 0 Operation Mode

FIFO 0 can be operated in blocking or in overwrite mode (see Section 3.4.2).

0= FIFO 0 blocking mode

1= FIFO 0 overwrite mode

**Bit 30:24 F0WM[6:0]:** Rx FIFO 0 Watermark

0= Watermark interrupt disabled

1-64= Level for Rx FIFO 0 watermark interrupt (**IR.RF0W**)

&gt;64= Watermark interrupt disabled

**Bit 22:16 F0S[6:0]:** Rx FIFO 0 Size

0= No Rx FIFO 0

1-64= Number of Rx FIFO 0 elements

&gt;64= Values greater than 64 are interpreted as 64

The Rx FIFO 0 elements are indexed from 0 to **F0S-1****Bit 15:2 F0SA[15:2]:** Rx FIFO 0 Start Address

Start address of Rx FIFO 0 in Message RAM (32-bit word address, see Figure 2).

**2.3.28 Rx FIFO 0 Status (RXF0S)**

R = Read; -n = value after reset

**Table 29 Rx FIFO 0 Status (address 0xA4)****Bit 25 RF0L:** Rx FIFO 0 Message LostThis bit is a copy of interrupt flag **IR.RF0L**. When **IR.RF0L** is reset, this bit is also reset.

0= No Rx FIFO 0 message lost

1= Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero

**Note: Overwriting the oldest message when RXF0C.FOOM = '1' will not set this flag.****Bit 24 F0F:** Rx FIFO 0 Full

0= Rx FIFO 0 not full

1= Rx FIFO 0 full

**Bit 21:16 F0PI[5:0]:** Rx FIFO 0 Put Index

Rx FIFO 0 write index pointer, range 0 to 63.

**Bit 13:8 F0GI[5:0]:** Rx FIFO 0 Get Index

Rx FIFO 0 read index pointer, range 0 to 63.

**Bit 6:0 F0FL[6:0]:** Rx FIFO 0 Fill Level

Number of elements stored in Rx FIFO 0, range 0 to 64.

**2.3.29 Rx FIFO 0 Acknowledge (RXF0A)**

R = Read, W = Write; -n = value after reset

**Table 30** Rx FIFO 0 Acknowledge (address 0xA8)**Bit 5:0 F0AI[5:0]: Rx FIFO 0 Acknowledge Index**

After the Host has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to **F0AI**. This will set the Rx FIFO 0 Get Index **RXF0S.F0GI** to **F0AI** + 1 and update the FIFO 0 Fill Level **RXF0S.F0FL**.

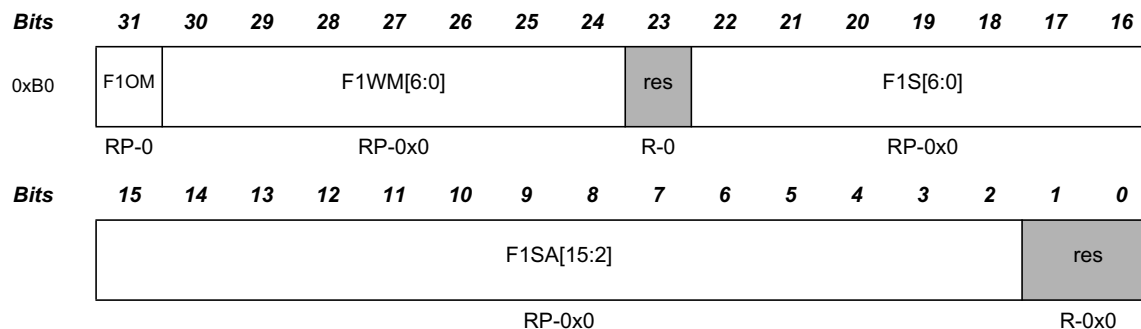

**2.3.30 Rx Buffer Configuration (RXBC)**

R = Read, P = Protected write; -n = value after reset

**Table 31** Rx Buffer Configuration (address 0xAC)**Bit 15:2 RBSA[15:2]: Rx Buffer Start Address**

Configures the start address of the Rx Buffers section in the Message RAM (32-bit word address). Also used to reference debug messages A,B,C.

### 2.3.31 Rx FIFO 1 Configuration (RXF1C)

R = Read, P = Protected write; -n = value after reset

Table 32 Rx FIFO 1 Configuration (address 0xB0)

**Bit 31 F1OM:** FIFO 1 Operation Mode

FIFO 1 can be operated in blocking or in overwrite mode (see Section 3.4.2).

0= FIFO 1 blocking mode

1= FIFO 1 overwrite mode

**Bit 30:24 F1WM[6:0]:** Rx FIFO 1 Watermark

0= Watermark interrupt disabled

1-64= Level for Rx FIFO 1 watermark interrupt (**IR.RF1W**)

>64= Watermark interrupt disabled

**Bit 22:16 F1S[6:0]:** Rx FIFO 1 Size

0= No Rx FIFO 1

1-64= Number of Rx FIFO 1 elements

>64= Values greater than 64 are interpreted as 64

The Rx FIFO 1 elements are indexed from 0 to **F1S** - 1

**Bit 15:2 F1SA[15:2]:** Rx FIFO 1 Start Address

Start address of Rx FIFO 1 in Message RAM (32-bit word address, see Figure 2).

### 2.3.32 Rx FIFO 1 Status (RXF1S)

R = Read; -n = value after reset

Table 33 Rx FIFO 1 Status (address 0xB4)

**Bits 31:30 DMS[1:0]:** Debug Message Status

00= Idle state, wait for reception of debug messages, DMA request is cleared

01= Debug message A received

10= Debug messages A, B received

11= Debug messages A, B, C received, DMA request is set

**Bit 25 RF1L:** Rx FIFO 1 Message Lost

This bit is a copy of interrupt flag **IR.RF1L**. When **IR.RF1L** is reset, this bit is also reset.

0= No Rx FIFO 1 message lost

1= Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero

**Note: Overwriting the oldest message when RXF1C.F1OM = '1' will not set this flag.**

**Bit 24 F1F:** Rx FIFO 1 Full

0= Rx FIFO 1 not full

1= Rx FIFO 1 full

**Bit 21:16 F1PI[5:0]:** Rx FIFO 1 Put Index

Rx FIFO 1 write index pointer, range 0 to 63.

**Bit 13:8 F1GI[5:0]:** Rx FIFO 1 Get Index

Rx FIFO 1 read index pointer, range 0 to 63.

**Bit 6:0 F1FL[6:0]:** Rx FIFO 1 Fill Level

Number of elements stored in Rx FIFO 1, range 0 to 64.

**2.3.33 Rx FIFO 1 Acknowledge (RXF1A)**

R = Read, W = Write; -n = value after reset

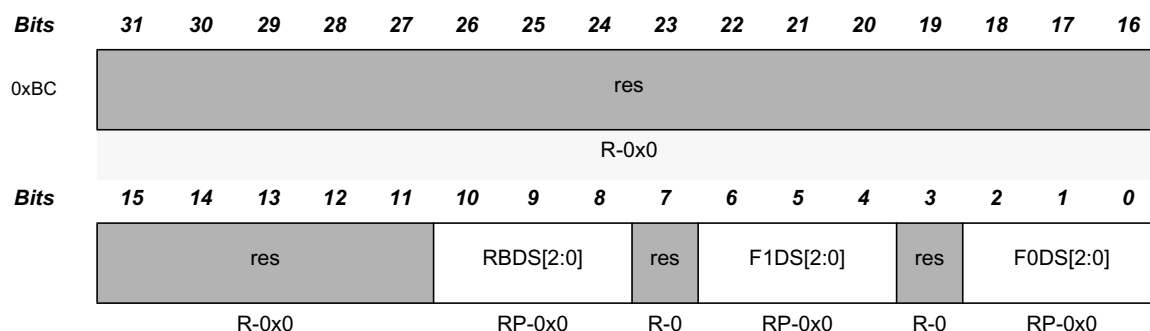

**Table 34 Rx FIFO 1 Acknowledge (address 0xB8)**

**Bit 5:0 F1AI[5:0]:** Rx FIFO 1 Acknowledge Index

After the Host has read a message or a sequence of messages from Rx FIFO 1 it has to write the buffer index of the last element read from Rx FIFO 1 to **F1AI**. This will set the Rx FIFO 1 Get Index **RXF1S.F1GI** to **F1AI** + 1 and update the FIFO 1 Fill Level **RXF1S.F1FL**.

### 2.3.34 Rx Buffer / FIFO Element Size Configuration (RXESC)

Configures the number of data bytes belonging to an Rx Buffer / Rx FIFO element. Data field sizes >8 bytes are intended for CAN FD operation only.

R = Read, P = Protected write, -U = undefined; -n = value after reset

Table 35 Rx Buffer / FIFO Element Size Configuration (address 0xBC)

#### Bits 10:8 RBDS[2:0]: Rx Buffer Data Field Size

000= 8 byte data field  
 001= 12 byte data field  
 010= 16 byte data field  
 011= 20 byte data field  
 100= 24 byte data field  
 101= 32 byte data field  
 110= 48 byte data field  
 111= 64 byte data field

#### Bits 6:4 F1DS[2:0]: Rx FIFO 1 Data Field Size

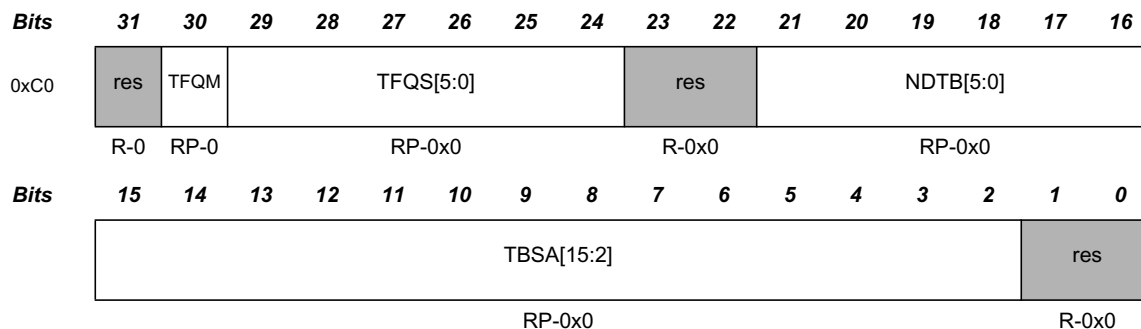

000= 8 byte data field  
 001= 12 byte data field  
 010= 16 byte data field  
 011= 20 byte data field  
 100= 24 byte data field  
 101= 32 byte data field  
 110= 48 byte data field  
 111= 64 byte data field

#### Bits 2:0 F0DS[2:0]: Rx FIFO 0 Data Field Size

000= 8 byte data field  
 001= 12 byte data field  
 010= 16 byte data field  
 011= 20 byte data field  
 100= 24 byte data field  
 101= 32 byte data field  
 110= 48 byte data field  
 111= 64 byte data field

**Note:** In case the data field size of an accepted CAN frame exceeds the data field size configured for the matching Rx Buffer or Rx FIFO, only the number of bytes as configured by RXESC are stored to the Rx Buffer resp. Rx FIFO element. The rest of the frame's data field is ignored.

### 2.3.35 Tx Buffer Configuration (TXBC)

R = Read, P = Protected write; -n = value after reset

Table 36 Tx Buffer Configuration (address 0xC0)

**Bit 30 TFQM:** Tx FIFO/Queue Mode

0= Tx FIFO operation

1= Tx Queue operation

**Bit 29:24 TFQS[5:0]:** Transmit FIFO/Queue Size

0= No Tx FIFO/Queue

1-32= Number of Tx Buffers used for Tx FIFO/Queue

>32= Values greater than 32 are interpreted as 32

**Bit 21:16 NDTB[5:0]:** Number of Dedicated Transmit Buffers

0= No Dedicated Tx Buffers

1-32= Number of Dedicated Tx Buffers

>32= Values greater than 32 are interpreted as 32

**Bit 15:2 TBSA[15:2]:** Tx Buffers Start Address

Start address of Tx Buffers section in Message RAM (32-bit word address, see Figure 2).

**Note:** Be aware that the sum of TFQS and NDTB may be not greater than 32. There is no check for erroneous configurations. The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.

### 2.3.36 Tx FIFO/Queue Status (TXFQS)

The Tx FIFO/Queue status is related to the pending Tx requests listed in register **TXBRP**. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (**TXBRP** not yet updated).

R = Read; -n = value after reset

Table 37 Tx FIFO/Queue Status (address 0xC4)

**Bit 21 TFQF:** Tx FIFO/Queue Full

0= Tx FIFO/Queue not full

1= Tx FIFO/Queue full

**Bit 20:16 TFQPI[4:0]:** Tx FIFO/Queue Put Index

Tx FIFO/Queue write index pointer, range 0 to 31.

**Bit 12:8 TFGI[4:0]:** Tx FIFO Get Index

Tx FIFO read index pointer, range 0 to 31. Read as zero when Tx Queue operation is configured (**TXBC.TFQM** = '1').

**Bit 5:0 TFFL[5:0]:** Tx FIFO Free Level

Number of consecutive free Tx FIFO elements starting from **TFGI**, range 0 to 32. Read as zero when Tx Queue operation is configured (**TXBC.TFQM** = '1')

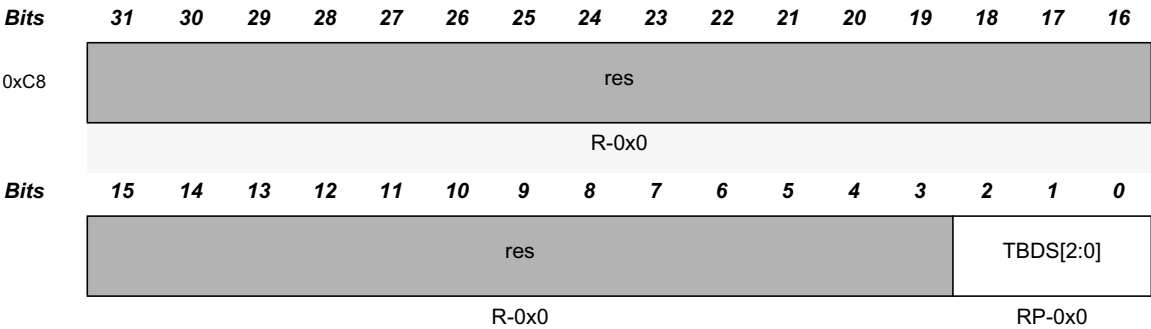

**Note:** In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Indices indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers.

**Example:** For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

2.3.37 Tx Buffer Element Size Configuration (TXESC)

Configures the number of data bytes belonging to a Tx Buffer element. Data field sizes > 8 bytes are intended for CAN FD operation only.

R = Read, P = Protected write, -U = undefined; -n = value after reset

Table 38 Tx Buffer Element Size Configuration (address 0xC8)

Bits 2:0 TBDS[2:0]: Tx Buffer Data Field Size

- 000= 8 byte data field
- 001= 12 byte data field
- 010= 16 byte data field
- 011= 20 byte data field
- 100= 24 byte data field
- 101= 32 byte data field
- 110= 48 byte data field
- 111= 64 byte data field

**Note:** In case the data length code DLC of a Tx Buffer element is configured to a value higher than the Tx Buffer data field size TXESC.TBDS, the bytes not defined by the Tx Buffer are transmitted as “0xCC” (padding bytes).

### 2.3.38 Tx Buffer Request Pending (TXBRP)

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0xCC	TRP31	TRP30	TRP29	TRP28	TRP27	TRP26	TRP25	TRP24	TRP23	TRP22	TRP21	TRP20	TRP19	TRP18	TRP17	TRP16
	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0

	TRP15	TRP14	TRP13	TRP12	TRP11	TRP10	TRP9	TRP8	TRP7	TRP6	TRP5	TRP4	TRP3	TRP2	TRP1	TRP0
	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0

R = Read; -n = value after reset

Table 39 Tx Buffer Request Pending (address 0xCC)

#### Bit 31:0 TRP[31:0]: Transmission Request Pending

Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register **TXBAR**. The bits are reset after a requested transmission has completed or has been cancelled via register **TXBCR**.

**TXBRP** bits are set only for those Tx Buffers configured via **TXBC**. After a **TXBRP** bit has been set, a Tx scan (see Section 3.5, *Tx Handling*) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID).

A cancellation request resets the corresponding transmission request pending bit of register **TXBRP**. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding **TXBRP** bit has been reset.

After a cancellation has been requested, a finished cancellation is signalled via **TXBCF**

- after successful transmission together with the corresponding **TXBTO** bit
- when the transmission has not yet been started at the point of cancellation
- when the transmission has been aborted due to lost arbitration
- when an error occurred during frame transmission

In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding **TXBCF** bit is set for all unsuccessful transmissions.

0= No transmission request pending

1= Transmission request pending

**Note:** *TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.*

### 2.3.39 Tx Buffer Add Request (TXBAR)

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0xD0	AR31	AR30	AR29	AR28	AR27	AR26	AR25	AR24	AR23	AR22	AR21	AR20	AR19	AR18	AR17	AR16
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

	AR15	AR14	AR13	AR12	AR11	AR10	AR9	AR8	AR7	AR6	AR5	AR4	AR3	AR2	AR1	AR0
	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0	RW-0

R = Read, W = Write; -n = value after reset

Table 40 Tx Buffer Add Request (address 0xD0)

#### Bit 31:0 AR[31:0]: Add Request

Each Tx Buffer has its own Add Request bit. Writing a '1' will set the corresponding Add Request bit; writing a '0' has no impact. This enables the Host to set transmission requests for multiple Tx Buffers with one write to **TXBAR**. **TXBAR** bits are set only for those Tx Buffers configured via **TXBC**. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.

0= No transmission request added

1= Transmission requested added

**Note:** If an add request is applied for a Tx Buffer with pending transmission request (corresponding **TXBRP** bit already set), this add request is ignored.

### 2.3.40 Tx Buffer Cancellation Request (TXBCR)

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1-32= Number of Tx Event FIFO elements

&gt;32= Values greater than 32 are interpreted as 32

The Tx Event FIFO elements are indexed from 0 to **EFS** - 1**Bit 15:2 EFSA[15:2]:** Event FIFO Start Address

Start address of Tx Event FIFO in Message RAM (32-bit word address, see Figure 2).

**2.3.46 Tx Event FIFO Status (TXEFS)**

R = Read; -n = value after reset

**Table 47** Tx Event FIFO Status (address 0xF4)**Bit 25 TEFL:** Tx Event FIFO Element LostThis bit is a copy of interrupt flag **IR.TEFL**. When **IR.TEFL** is reset, this bit is also reset.

0= No Tx Event FIFO element lost

1= Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero.

**Bit 24 EFF:** Event FIFO Full

0= Tx Event FIFO not full

1= Tx Event FIFO full

**Bit 20:16 EFPI[4:0]:** Event FIFO Put Index

Tx Event FIFO write index pointer, range 0 to 31.

**Bit 12:8 EFGI[4:0]:** Event FIFO Get Index

Tx Event FIFO read index pointer, range 0 to 31.

**Bit 5:0 EFFL[5:0]:** Event FIFO Fill Level

Number of elements stored in Tx Event FIFO, range 0 to 32.

**2.3.47 Tx Event FIFO Acknowledge (TXEFA)**

R = Read, W = Write; -n = value after reset

**Table 48** Tx Event FIFO Acknowledge (address 0xF8)**Bit 4:0 EFAI[4:0]:** Event FIFO Acknowledge IndexAfter the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to **EFAI**. This will set the Tx Event FIFO Get Index **TXEFS.EFGI** to **EFAI + 1** and update the Event FIFO Fill Level **TXEFS.EFFL**.

## 2.4 Message RAM

For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M\_CAN module.

**Note:** *In case the Message RAM is equipped with parity or ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing e.g. 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).*

### 2.4.1 Message RAM Configuration

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M\_CAN module can be configured to allocate up to 4352 words in the Message RAM. It is not necessary to configure each of the sections listed in Figure 2, nor is there any restriction with respect to the sequence of the sections.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via **RXESC.F0DS**, **RXESC.F1DS**, **RXESC.RBDS**, and **TXESC.TBDS**.

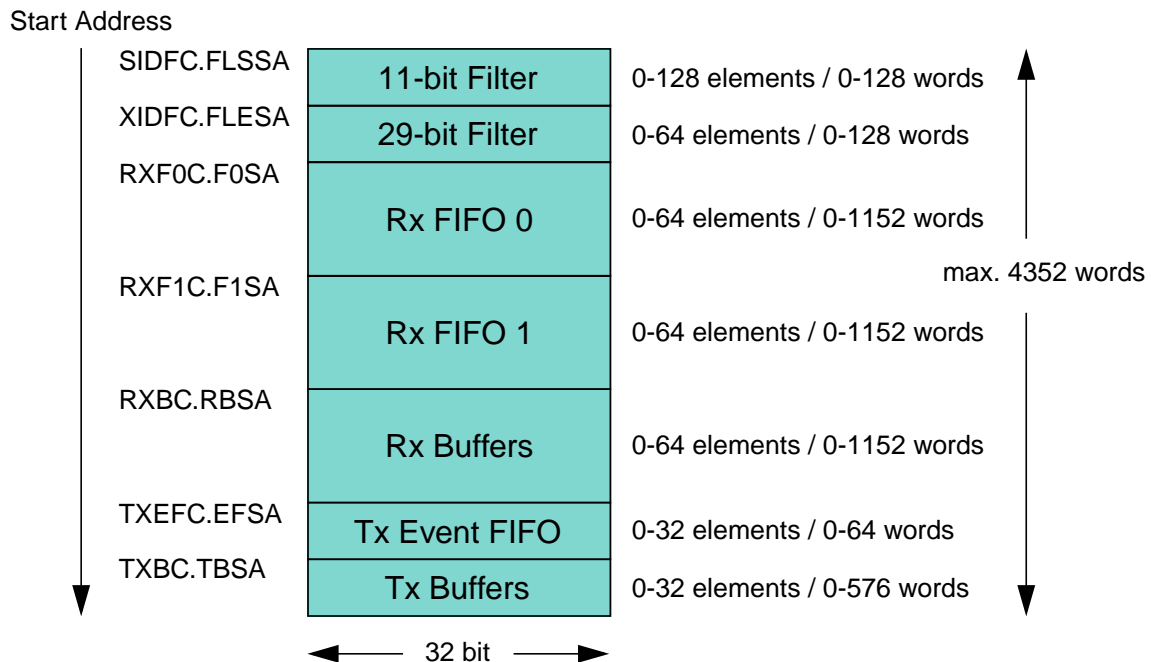

Figure 2 Message RAM Configuration

When the M\_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

**Note:** *The M\_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.*

## 2.4.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in Table 49 below. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

**R1A:** When no TSU is used (**CCCR.UTSU** = '0'), **R1A.RXTS[15:0]** holds the 16-bit timestamp generated by the M\_CAN's internal timestamping logic.

**R1B:** When a TSU is used (**CCCR.UTSU** = '1') and when bit **SSYNC/ESYNC** of the matching filter element is set, **R1B.TSC** = '1' and **R1B.RXTSP[3:0]** holds the number of the TSU's Timestamp register which holds the 32-bit timestamp captured by the TSU. Else **R1B.TSC** = '0' and **R1B.RXTSP[3:0]** is not valid.

Table 49 Rx Buffer and FIFO Element

**R0 Bit 31 ESI:** Error State Indicator

- 0= Transmitting node is error active
- 1= Transmitting node is error passive

**R0 Bit 30 XTD:** Extended Identifier

- Signals to the Host whether the received frame has a standard or extended identifier.
- 0= 11-bit standard identifier
  - 1= 29-bit extended identifier

**R0 Bit 29 RTR:** Remote Transmission Request

- Signals to the Host whether the received frame is a data frame or a remote frame.
- 0= Received frame is a data frame
  - 1= Received frame is a remote frame

**Note:** *There are no remote frames in CAN FD format. In CAN FD frames (FDF = 1'), the dominant RRS (Remote Request Substitution) bit replaces bit RTR (Remote Transmission Request).*

**R0 Bits 28:0 ID[28:0]:** Identifier

Standard or extended identifier depending on bit **XTD**. A standard identifier is stored into **ID[28:18]**.

**R1A/B Bit 31 ANMF:** Accepted Non-matching Frame

Acceptance of non-matching frames may be enabled via **GFC.ANFS** and **GFC.ANFE**.

0= Received frame matching filter index **FIDX**

1= Received frame did not match any Rx filter element

**R1A/B Bits 30:24 FIDX[6:0]:** Filter Index

0-127=Index of matching Rx acceptance filter element (invalid if **ANMF** = '1').

Range is 0 to **SIDFC.LSS** - 1 resp. **XIDFC.LSE** - 1.

**R1A/B Bit 21 FDF:** FD Format

0= Classical CAN frame format

1= CAN FD frame format (new DLC-coding and CRC)

**R1A/B Bit 20 BRS:** Bit Rate Switch

0= Frame received without bit rate switching

1= Frame received with bit rate switching

**R1A/B Bits 19:16 DLC[3:0]:** Data Length Code

0-8= CAN + CAN FD: received frame has 0-8 data bytes

9-15= CAN: received frame has 8 data bytes

9-15= CAN FD: received frame has 12/16/20/24/32/48/64 data bytes

**R1A Bits 15:0 RXTS[15:0]:** Rx Timestamp

Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler **TSCC.TCP**.

**R1B Bit 4 TSC:** Timestamp Captured

0= No timestamp captured

1= Timestamp captured and stored in TSU Timestamp register referenced by **R1B.RXTSP**

**R1B Bits 3:0 RXTSP[3:0]:** Rx Timestamp Pointer

Number of TSU Time Stamp register (TS0..15) where the related timestamp is stored.

**R2 Bits 31:24 DB3[7:0]:** Data Byte 3

**R2 Bits 23:16 DB2[7:0]:** Data Byte 2

**R2 Bits 15:8 DB1[7:0]:** Data Byte 1

**R2 Bits 7:0 DB0[7:0]:** Data Byte 0

**R3 Bits 31:24 DB7[7:0]:** Data Byte 7

**R3 Bits 23:16 DB6[7:0]:** Data Byte 6

**R3 Bits 15:8 DB5[7:0]:** Data Byte 5

**R3 Bits 7:0 DB4[7:0]:** Data Byte 4

... : ...

**Rn Bits 31:24 DBm[7:0]:** Data Byte m

**Rn Bits 23:16 DBm-1[7:0]:** Data Byte m-1

**Rn Bits 15:8 DBm-2[7:0]:** Data Byte m-2

**Rn Bits 7:0 DBm-3[7:0]:** Data Byte m-3

**Note:** Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words ( $Rn = 2 \dots 17$ ) are used for storage of a CAN message's data field.

### 2.4.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration **TXBC.TFQS** and **TXBC.NDTB**. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

	31	24	23	16	15	8	7	0
T0	ESI	XTD	RTR	ID[28:0]

T2	DB3[7:0]			DB2[7:0]			DB1[7:0]	
T3	DB7[7:0]			DB6[7:0]			DB5[7:0]	
...	...			...			...	
Tn	DBm[7:0]			DBm-1[7:0]			DBm-2[7:0]	

Table 50 Tx Buffer Element

**T0 Bit 31 ESI:** Error State Indicator

0= ESI bit in CAN FD format depends only on error passive flag

1= ESI bit in CAN FD format transmitted recessive

**Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive

**T0 Bit 30 XTD:** Extended Identifier

0= 11-bit standard identifier

1= 29-bit extended identifier

**T0 Bit 29 RTR:** Remote Transmission Request

0= Transmit data frame

1= Transmit remote frame

**Note:** When  $RTR = 1$ , the M\_CAN transmits a remote frame according to ISO 11898-1:2015, even if  $CCCR.FDOE$  enables the transmission in CAN FD format.

**T0 Bits 28:0 ID[28:0]:** Identifier

Standard or extended identifier depending on bit **XTD**. A standard identifier has to be written to **ID[28:18]**.

**T1 Bits 31:24 MM[7:0]:** Message Marker

Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

**T1 Bit 23 EFC:** Event FIFO Control

- 0= Don't store Tx events
- 1= Store Tx events

**T1 Bit 22 TSCE:** Time Stamp Capture Enable for TSU

Only available when  $CCCR.UTSU = '1'$ . When this bit is set and the message is transmitted, a pulse with the duration of one **m\_can\_hclk** period is generated at output **m\_can\_tsrx** to signal the transmission of a Sync message to the Timestamping Unit (TSU) connected to the M\_CAN.

- 0= Time Stamp Capture disabled
- 1= Time Stamp Capture enabled

**T1 Bit 21 FDF:** FD Format

- 0= Frame transmitted in Classic CAN format
- 1= Frame transmitted in CAN FD format

**T1 Bit 20 BRS:** Bit Rate Switch

- 0= CAN FD frames transmitted without bit rate switching
- 1= CAN FD frames transmitted with bit rate switching

**Note:** Bits **ESI**, **FDF**, and **BRS** are only evaluated when CAN FD operation is enabled  $CCCR.FDOE = 1$ . Bit **BRS** is only evaluated when in addition  $CCCR.BRSE = 1$ .

**T1 Bits 19:16 DLC[3:0]:** Data Length Code

- 0-8= CAN + CAN FD: transmit frame has 0-8 data bytes
- 9-15= CAN: transmit frame has 8 data bytes
- 9-15= CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes

**T1 Bits 15:8 MM[15:8]:** Message Marker

High byte of Wide Message Marker, written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status. Available only when  $CCCR.WMM = 1$  or when  $CCCR.UTSU = 1$ .

**T2 Bits 31:24 DB3[7:0]:** Data Byte 3

**T2 Bits 23:16 DB2[7:0]:** Data Byte 2

**T2 Bits 15:8 DB1[7:0]:** Data Byte 1

**T2 Bits 7:0 DB0[7:0]:** Data Byte 0

**T3 Bits 31:24 DB7[7:0]:** Data Byte 7

**T3 Bits 23:16 DB6[7:0]:** Data Byte 6

**T3 Bits 15:8 DB5[7:0]:** Data Byte 5

**T3 Bits 7:0 DB4[7:0]:** Data Byte 4

... : ...

**Tn Bits 31:24 DBm[7:0]:** Data Byte m

**Tn Bits 23:16 DBm-1[7:0]:** Data Byte m-1

**Tn Bits 15:8 DBm-2[7:0]:** Data Byte m-2

**Tn Bits 7:0 DBm-3[7:0]:** Data Byte m-3

**Note:** Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words ( $Tn = 2 \dots 17$ ) are used for storage of a CAN message's data field.

#### 2.4.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register **TXEFS**.

**E1A:** When **CCCR.WMM** = '0' and no TSU is used (**CCCR.UTSU** = '0'), **E1A.TXTS[15:0]** holds the 16-bit timestamp generated by the M\_CAN's internal timestamping logic.

**E1B:** When 16-bit Message Markers are enabled (**CCCR.WMM** = '1') or when **CCCR.UTSU** = '1', **E1B.MM[15:8]** holds the upper 8 bit of the Wide Message Marker. When a TSU is used (**CCCR.UTSU** = '1') and when bit **TSCE** of the related Tx Buffer element is set, **E1B.TSC** = '1' and **E1B.TXTSP[3:0]** holds the number of the TSU's Timestamp register which holds the 32-bit timestamp captured by the TSU. Else **E1B.TSC** = '0' and **E1B.TXTSP[3:0]** is not valid.

	31	24	23	16	15	8	7	0

Table 51 Tx Event FIFO Element

**E0 Bit 31 ESI:** Error State Indicator

0= Transmitting node is error active

1= Transmitting node is error passive

**E0 Bit 30 XTD:** Extended Identifier

0= 11-bit standard identifier

1= 29-bit extended identifier

**E0 Bit 29 RTR:** Remote Transmission Request

0= Data frame transmitted

1= Remote frame transmitted

**E0 Bits 28:0 ID[28:0]:** Identifier

Standard or extended identifier depending on bit **XTD**. A standard identifier is stored into **ID[28:18]**.

**E1A/B Bits 31:24 MM[7:0]:** Message Marker

Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.

**E1A/B Bit 23:22 ET[1:0]: Event Type**

- 00= Reserved
- 01= Tx event
- 10= Transmission in spite of cancellation (always set for transmissions in DAR mode)
- 11= Reserved

**E1A/B Bit 21 FDF: FD Format**

- 0= Classical CAN frame format
- 1= CAN FD frame format (new DLC-coding and CRC)

**E1A/B Bit 20 BRS: Bit Rate Switch**

- 0= Frame transmitted without bit rate switching
- 1= Frame transmitted with bit rate switching

**E1A/B Bits 19:16 DLC[3:0]: Data Length Code**

- 0-8= CAN + CAN FD: frame with 0-8 data bytes transmitted
- 9-15= CAN: frame with 8 data bytes transmitted
- 9-15= CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted

**E1A Bits 15:0 TXTS[15:0]: Tx Timestamp**

Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler **TSCC.TCP**.

**E1B Bits 15:8 MM[15:8]: Message Marker**

High byte of Wide Message Marker, written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

**E1B Bit 4 TSC: Timestamp Captured**

- 0= No timestamp captured
- 1= Timestamp captured and stored in TSU Timestamp register referenced by **E1B.TXTSP**

**E1B Bits 3:0 TXTSP[3:0]: Tx Timestamp Pointer**

Number of TSU Time Stamp register (TS0..15) where the related timestamp is stored.

**2.4.5 Standard Message ID Filter Element**

Up to 128 filter elements can be configured for 11-bit IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address **SIDFC.FLSSA** plus the index of the filter element (0...127).

**Table 52** Standard Message ID Filter Element

**Bits 31:30 SFT[1:0]: Standard Filter Type**

- 00= Range filter from **SFID1** to **SFID2** (**SFID2** ≥ **SFID1**)
- 01= Dual ID filter for **SFID1** or **SFID2**
- 10= Classic filter: **SFID1** = filter, **SFID2** = mask
- 11= Filter element disabled

**Note:** With **SFT** = "11" the filter element is disabled and the acceptance filtering continues (same behaviour as with **SFEC** = "000")

**Bit 29:27 SFEC[2:0]: Standard Filter Element Configuration**

All enabled filter elements are used for acceptance filtering of 11-bit ID frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If **SFEC** = "100", "101", or "110" a match sets interrupt flag **IR.HPM** and, if enabled, an interrupt is generated. In this case register **HPMS** is updated with the status of the priority match.

000= Disable filter element

001= Store in Rx FIFO 0 if filter matches

010= Store in Rx FIFO 1 if filter matches

011= Reject ID if filter matches, not intended to be used with Sync messages

100= Set priority if filter matches, not intended to be used with Sync messages, no storage

101= Set priority and store in FIFO 0 if filter matches

110= Set priority and store in FIFO 1 if filter matches

111= Store into Rx Buffer or as debug message, configuration of **SFT[1:0]** ignored

**Bits 26:16 SFID1[10:0]: Standard Filter ID 1**

First ID of standard ID filter element. When filtering for Rx Buffers, Sync messages, or for debug messages this field defines the ID of the message to be stored. The received identifiers must match exactly, no masking mechanism is used.

**Bit 15 SSYNC: Standard Sync Message**

Only evaluated when **CCCR.UTSU** = '1'. When this bit is set and a matching message is received, a pulse with the duration of one **m\_can\_hclk** period is generated at output **m\_can\_tsr** to signal the reception of a Sync message to the Timestamping Unit (TSU) connected to the M\_CAN.

0= Timestamping for the matching Sync message disabled

1= Timestamping for the matching Sync message enabled

**Note:** *The generation of a pulse at output **m\_can\_tsr** is independent of whether the matching received message is stored or not. E.g. if a message is received for one of the two Rx FIFOs and the FIFO is full and operated in blocking mode, the pulse is generated but the message itself is not stored. In this case the timestamp captured by the TSU does not relate to a message in the M\_CAN's Message RAM.*

**Bits 10:0 SFID2[10:0]: Standard Filter ID 2**

This bit field has a different meaning depending on the configuration of **SFEC**:

1) **SFEC** = "001"..."110" Second ID of standard ID filter element

2) **SFEC** = "111" Filter for Rx Buffers or for debug messages

**SFID2[10:9]** decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence.

00= Store message into an Rx Buffer

01= Debug Message A

10= Debug Message B

11= Debug Message C

**SFID2[8:6]** is used to control the filter event pins **m\_can\_fe[2:0]** at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one **m\_can\_hclk** period in case the filter matches.

**SFID2[5:0]** defines the offset to the Rx Buffer Start Address **RXBC.RBSA** for storage of a matching message.

### 2.4.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address **XIDFC.FLESA** plus two times the index of the filter element (0...63).

	31		24		23	16		15	8		7	0	
F0	EFEC[2:0]		EFID1[28:0]										
F1	EFT[1:0]	ESYNC	EFID2[28:0]										

Table 53 Extended Message ID Filter Element

#### F0 Bit 31:29 EFEC[2:0]: Extended Filter Element Configuration

All enabled filter elements are used for acceptance filtering of 29-bit ID frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If **EFEC** = "100", "101", or "110" a match sets interrupt flag **IR.HPM** and, if enabled, an interrupt is generated. In this case register **HPMS** is updated with the status of the priority match.

000= Disable filter element

001= Store in Rx FIFO 0 if filter matches

010= Store in Rx FIFO 1 if filter matches

011= Reject ID if filter matches, not intended to be used with Sync messages

100= Set priority if filter matches, not intended to be used with Sync messages, no storage

101= Set priority and store in FIFO 0 if filter matches

110= Set priority and store in FIFO 1 if filter matches

111= Store into Rx Buffer or as debug message, configuration of **EFT[1:0]** ignored

#### F0 Bits 28:0 EFID1[28:0]: Extended Filter ID 1

First ID of extended ID filter element. When filtering for Rx Buffers, Sync messages, or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only **XIDAM** masking mechanism (see Section 3.4.1.5) is used.

#### F1 Bits 31:30 EFT[1:0]: Extended Filter Type

00= Range filter from **EFID1** to **EFID2** (**EFID2** ≥ **EFID1**)

01= Dual ID filter for **EFID1** or **EFID2**

10= Classic filter: **EFID1** = filter, **EFID2** = mask

11= Range filter from **EFID1** to **EFID2** (**EFID2** ≥ **EFID1**), **XIDAM** mask not applied

#### F1 Bit 29 ESYNC: Extended Sync Message

Only evaluated when **CCCR.UTSU** = '1'. When this bit is set and a matching message is received, a pulse with the duration of one **m\_can\_hclk** period is generated at output **m\_can\_tsr** to signal the reception of a Sync message to the Timestamping Unit (TSU) connected to the M\_CAN.

0= Timestamping for the matching Sync message disabled

1= Timestamping for the matching Sync message enabled

**Note:** The generation of a pulse at output **m\_can\_tsr** is independent of whether the matching received message is stored or not. E.g. if a message is received for one of the two Rx FIFOs and the FIFO is full and operated in blocking mode, the pulse is generated but the message itself is not stored. In this case the timestamp captured by the TSU does not relate to a message in the M\_CAN's Message RAM.

**F1 Bits 28:0 EFID2[28:0]:** Extended Filter ID 2

This bit field has a different meaning depending on the configuration of **EFEC**:

- 1) **EFEC** = "001"... "110" Second ID of extended ID filter element
- 2) **EFEC** = "111" Filter for Rx Buffers or for debug messages

**EFID2[10:9]** decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence.

00= Store message into an Rx Buffer

01= Debug Message A

10= Debug Message B

11= Debug Message C

**EFID2[8:6]** is used to control the filter event pins **m\_can\_fe[2:0]** at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one **m\_can\_hclk** period in case the filter matches.

**EFID2[5:0]** defines the offset to the Rx Buffer Start Address **RXBC.RBSA** for storage of a matching message.

# Chapter 3.

## 3. Functional Description

### 3.1 Operating Modes

#### 3.1.1 Software Initialization

Software initialization is started by setting bit **CCCR.INIT**, either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going *Bus\_Off*. While **CCCR.INIT** is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output **m\_can\_tx** is *recessive* (HIGH). The counters of the Error Management Logic EML are unchanged. Setting **CCCR.INIT** does not change any configuration register. Resetting **CCCR.INIT** finishes the software initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive *recessive* bits ( $\equiv$  *Bus\_Idle*) before it can take part in bus activities and start the message transfer.

Access to the M\_CAN configuration registers is only enabled when both bits **CCCR.INIT** and **CCCR.CCE** are set (protected write).

**CCCR.CCE** can only be set/reset while **CCCR.INIT** = '1'. **CCCR.CCE** is automatically reset when **CCCR.INIT** is reset.

The following registers are reset when **CCCR.CCE** is set

- **HPMS** - High Priority Message Status
- **RXF0S** - Rx FIFO 0 Status
- **RXF1S** - Rx FIFO 1 Status
- **TXFQS** - Tx FIFO/Queue Status
- **TXBRP** - Tx Buffer Request Pending
- **TXBTO** - Tx Buffer Transmission Occurred
- **TXBCF** - Tx Buffer Cancellation Finished
- **TXEFS** - Tx Event FIFO Status

The Timeout Counter value **TOCV.TOC** is preset to the value configured by **TOCC.TOP** when **CCCR.CCE** is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while **CCCR.CCE** = '1'.

The following registers are only writeable while **CCCR.CCE** = '0'

- **TXBAR** - Tx Buffer Add Request
- **TXBCR** - Tx Buffer Cancellation Request

**CCCR.TEST** and **CCCR.MON** can only be set by the Host while **CCCR.INIT** = '1' and **CCCR.CCE** = '1'. Both bits may be reset at any time. **CCCR.DAR** can only be set/reset while **CCCR.INIT** = '1' and **CCCR.CCE** = '1'.

**Note:** *In case the Message RAM is equipped with parity or ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing e.g. 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).*

### 3.1.2 Normal Operation

Once the M\_CAN is initialized and **CCCR.INIT** is reset to zero, the M\_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into a dedicated Rx Buffer or into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

### 3.1.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as **FDF** bit. **FDF** = *recessive* signifies a CAN FD frame, **FDF** = *dominant* signifies a Classic CAN frame. In a CAN FD frame, the two bits following **FDF**, **res** and **BRS**, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by **res** = *dominant* and **BRS** = *recessive*. The coding of **res** = *recessive* is reserved for future expansion of the protocol. In case the M\_CAN receives a frame with **FDF** = *recessive* and **res** = *recessive*, it will signal a Protocol Exception Event by setting bit **PSR.PXE**. When Protocol Exception Handling is enabled (**CCCR.PXHD** = '0'), this causes the operation state to change from Receiver (**PSR.ACT** = "10") to Integrating (**PSR.ACT** = "00") at the next sample point. In case Protocol Exception Handling is disabled (**CCCR.PXHD** = '1'), the M\_CAN will treat a *recessive* **res** bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming **CCCR.FDOE**. In case **CCCR.FDOE** = '1', transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit **FDF** in the respective Tx Buffer element. With **CCCR.FDOE** = '0', received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit **FDF** of a Tx Buffer element is set. **CCCR.FDOE** and **CCCR.BRSE** can only be changed while **CCCR.INIT** and **CCCR.CCE** are both set.

With **CCCR.FDOE** = '0', the setting of bits **FDF** and **BRS** is ignored and frames are transmitted in Classic CAN format. With **CCCR.FDOE** = '1' and **CCCR.BRSE** = '0', only bit **FDF** of a Tx Buffer element is evaluated. With **CCCR.FDOE** = '1' and **CCCR.BRSE** = '1', transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits **FDF** and **BRS** set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to Table 54 below.

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

Table 54 Coding of DLC in CAN FD

In CAN FD frames, the bit timing will be switched inside the frame, after the **BRS** (Bit Rate Switch) bit, if this bit is *recessive*. Before the **BRS** bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the Nominal Bit Timing & Prescaler Register **NBTP**. In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing & Prescaler Register **DBTP**. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (**m\_can\_cclk**). Example: with a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the bit **ESI** (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, **ESI** is transmitted *recessive*, else it is transmitted *dominant*.

### 3.1.4 Transmitter Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin **m\_can\_tx** the M\_CAN receives the transmitted data from its local CAN transceiver via pin **m\_can\_rx**. The received data is delayed by the transmitter delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

#### 3.1.4.1 Description

The M\_CAN's protocol unit has implemented a delay compensation mechanism to compensate the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in ISO 11898-1:2015. It is enabled by setting bit **DBTP.TDC**.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M\_CAN's transmit output **m\_can\_tx** through the transceiver to the receive input **m\_can\_rx** plus the transmitter delay compensation offset as configured by **TDCR.TDCO**. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

**PSR.TDCV** shows the actual transmitter delay compensation value. **PSR.TDCV** is cleared when **CCCR.INIT** is set and is updated at each transmission of an FD frame while **DBTP.TDC** is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M\_CAN:

- The sum of the measured delay from **m\_can\_tx** to **m\_can\_rx** and the configured transmitter delay compensation offset **TDCR.TDCO** has to be less than 6 bit times in the data phase.
- The sum of the measured delay from **m\_can\_tx** to **m\_can\_rx** and the configured transmitter delay compensation offset **TDCR.TDCO** has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs

### 3.1.4.2 Transmitter Delay Compensation Measurement

If transmitter delay compensation is enabled by programming **DBTP.TDC** = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit **FDF** to bit **res**. The measurement is stopped when this edge is seen at the receive input **m\_can\_rx** of the transmitter. The resolution of this measurement is one mtq.

Figure 3 Transmitter Delay Measurement

To avoid that a dominant glitch inside the received **FDF** bit ends the delay compensation measurement before the falling edge of the received **res** bit, resulting in a too early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming **TDCR.TDCF**. This defines a minimum value for the SSP position. Dominant edges on **m\_can\_rx**, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least **TDCR.TDCF** AND **m\_can\_rx** is low.

**Note:** The M\_CAN always performs Transmitter Delay measurement, it does not support the configuration of a static (fixed) Transmitter Delay.

### 3.1.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (**ECR.REC**, **ECR.TEC**) are frozen while Error Logging (**ECR.CEL**) is active. The Host can set the M\_CAN into Restricted Operation mode by setting bit **CCCR.ASM**. The bit can only be set by the Host when both **CCCR.CCE** and **CCCR.INIT** are set to '1'. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset **CCCR.ASM**.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

If the M\_CAN is connected to a Clock Calibration on CAN unit, **CCCR.ASM** is controlled by input **m\_can\_cok**. In case **m\_can\_cok** switches to '0', bit **CCCR.ASM** is set. When **m\_can\_cok** switches back to '1', bit **CCCR.ASM** returns to the previously written value. When there is no Clock Calibration on CAN unit connected input **m\_can\_cok** is hardwired to '1'.

**Note:** *The Restricted Operation Mode must not be combined with the Loop Back Mode (internal or external).*

### 3.1.6 Bus Monitoring Mode

The M\_CAN is set in Bus Monitoring Mode by programming **CCCR.MON** to *one*. In Bus Monitoring Mode (see ISO 11898-1:2015, 10.14 Bus monitoring), the M\_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only *recessive* bits on the CAN bus. If the M\_CAN is required to send a *dominant* bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M\_CAN monitors this *dominant* bit, although the CAN bus may remain in *recessive* state. In Bus Monitoring Mode register **TXBRP** is held in reset state.

The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of *dominant* bits. Figure 5 shows the connection of signals **m\_can\_tx** and **m\_can\_rx** to the M\_CAN in Bus Monitoring Mode.

Figure 4 Pin Control in Bus Monitoring Mode

### 3.1.7 Disabled Automatic Retransmission

According to the CAN Specification (see ISO 11898-1:2015, 8.3.4 Recovery Management), the M\_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1:2015, chapter 9.2, the automatic retransmission may be disabled via **CCCR.DAR**.

#### 3.1.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit **TXBRP.TRPx** is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:  
Corresponding Tx Buffer Transmission Occurred bit **TXBTO.TOx** set  
Corresponding Tx Buffer Cancellation Finished bit **TXBCF.CFx** not set
- Successful transmission in spite of cancellation:  
Corresponding Tx Buffer Transmission Occurred bit **TXBTO.TOx** set  
Corresponding Tx Buffer Cancellation Finished bit **TXBCF.CFx** set
- Arbitration lost or frame transmission disturbed:  
Corresponding Tx Buffer Transmission Occurred bit **TXBTO.TOx** not set  
Corresponding Tx Buffer Cancellation Finished bit **TXBCF.CFx** set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type **ET** = "10" (transmission in spite of cancellation).

#### 3.1.8 Power Down (Sleep Mode)

The M\_CAN can be set into power down mode controlled by input signal **m\_can\_clkstop\_req** or via CC Control Register **CCCR.CSR**. As long as the clock stop request signal **m\_can\_clkstop\_req** is active, bit **CCCR.CSR** is read as *one*.

When all pending transmission requests have completed, the M\_CAN waits until bus idle state is detected. Then the M\_CAN sets then **CCCR.INIT** to *one* to prevent any further CAN transfers. Now the M\_CAN acknowledges that it is ready for power down by setting output signal **m\_can\_clkstop\_ack** to *one* and **CCCR.CSA** to *one*. Before the module clocks **m\_can\_hclk** and **m\_can\_cclk** are switched off, further register accesses can be made except for **CCCR.INIT** which is held at *one*.

**Note:** *In case of a heavily disturbed CAN bus, it may happen that idle state is never reached and CCCR.INIT is therefore not set by the M\_CAN. This situation can be detected by polling PSR.ACT. In case the M\_CAN does not enter idle state, the software can write CCCR.INIT = '1' which stops CAN communication of the M\_CAN immediately, regardless whether there is a transmission/reception ongoing or not.*

To leave power down mode, the application has to turn on the module clocks before resetting signal **m\_can\_clkstop\_req** resp. CC Control Register flag **CCCR.CSR**. The M\_CAN will acknowledge this by resetting output signal **m\_can\_clkstop\_ack** and resetting **CCCR.CSA**. Afterwards, the application can restart CAN communication by resetting bit **CCCR.INIT**.

### 3.1.9 Test Modes

To enable write access to register **TEST** (see Section 2.3.5), bit **CCCR.TEST** has to be set to *one*. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin **m\_can\_tx** by programming **TEST.TX**. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M\_CAN's bit timing and it can drive constant dominant or recessive values. The actual value at pin **m\_can\_rx** can be read from **TEST.RX**. Both functions can be used to check the CAN bus' physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to **TEST.TX** until the new configuration is visible at output pin **m\_can\_tx**. This applies also when reading input pin **m\_can\_rx** via **TEST.RX**.

**Note:** *Test modes should be used for production tests or self test only. The software control for pin m\_can\_tx interferes with all CAN protocol functions. It is not recommended to use test modes for application.*

#### 3.1.9.1 External Loop Back Mode

The M\_CAN can be set in External Loop Back Mode by programming **TEST.LBCK** to *one*. In Loop Back Mode, the M\_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into an Rx Buffer or an Rx FIFO. Figure 5 shows the connection of signals **m\_can\_tx** and **m\_can\_rx** to the M\_CAN in External Loop Back Mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M\_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back Mode. In this mode the M\_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the **m\_can\_rx** input pin is disregarded by the M\_CAN. The transmitted messages can be monitored at the **m\_can\_tx** pin.

#### 3.1.9.2 Internal Loop Back Mode

Internal Loop Back Mode is entered by programming bits **TEST.LBCK** and **CCCR.MON** to *one*. This mode can be used for a "Hot Selftest", meaning the M\_CAN can be tested without affecting a running CAN system connected to the pins **m\_can\_tx** and **m\_can\_rx**. In this mode pin **m\_can\_rx** is disconnected from the M\_CAN and pin **m\_can\_tx** is held *recessive*. Figure 5 shows the connection of **m\_can\_tx** and **m\_can\_rx** to the M\_CAN in case of Internal Loop Back Mode.

Figure 5 Pin Control in Loop Back Modes

## 3.2 Timestamp Generation

### 3.2.1 Internal Timestamp Generation

For internal timestamp generation the M\_CAN supplies a 16-bit wrap-around counter. A prescaler **TSCC.TCP** can be configured to clock the counter in multiples of CAN bit times (1...16). The counter is readable via **TSCV.TSC**. A write access to register **TSCV** resets the counter to zero. When the timestamp counter wraps around interrupt flag **IR.TSW** is set.

On start of frame reception / transmission (SOF) the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (**RXTS[15:0]**) or Tx Event FIFO (**TXTS[15:0]**) element.

By programming bit **TSCC.TSS**, the external 16-bit timebase vector input (**m\_can\_ext\_ts[15:0]**) of the M\_CAN can be captured as timestamp instead of the internal 16-bit counter.

### 3.2.2 Timestamp Generation by use of an external TSU

An external Time Stamping Unit (TSU) for generation of 32-bit timestamps according to CiA 603 can be connected to the M\_CAN's TSU Interface. External timestamping is enabled when **CCCR.UTSU** = '1'.

To filter for Sync messages a Standard or Extended Filter Element has to be configured with the Sync message's ID and bit **SSYNC** resp. **ESYNC** set to one.

At the end of frame reception / transmission (EOF), the timestamp is captured by the TSU, controlled by the M\_CAN's output signals **m\_can\_tsr** and **m\_can\_tstx**. The number of the TSU's Timestamp register which holds the captured timestamp is signalled to the M\_CAN by **m\_can\_tsp[2:0]** and is stored into the related Rx Buffer / Rx FIFO element (**R1B.RXTSP[2:0]**) resp. Tx Event FIFO element (**E1B.TXTSP[2:0]**). For a detailed description see the TSU User's Manual.

## 3.3 Timeout Counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M\_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by **TSCC.TCP** as the Timestamp Counter. The Timeout Counter is configured via register **TOCC**. The actual counter value can be read from **TOCV.TOC**. The Timeout Counter can only be started while **CCCR.INIT** = '0'. It is stopped when **CCCR.INIT** = '1', e.g. when the M\_CAN enters *Bus\_Off* state.

The operation mode is selected by **TOCC.TOS**. When operating in Continuous Mode, the counter starts when **CCCR.INIT** is reset. A write to **TOCV** presets the counter to the value configured by **TOCC.TOP** and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by **TOCC.TOP**. Down-counting is started when the first FIFO element is stored. Writing to **TOCV** has no effect.

When the counter reaches zero, interrupt flag **IR.TOO** is set. In Continuous Mode, the counter is immediately restarted at **TOCC.TOP**.

**Note:** *The clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN Core. If the bit rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.*

### 3.4 Rx Handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

#### 3.4.1 Acceptance Filtering

The M\_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - range filter (from - to)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration **GFC**
- Standard ID Filter Configuration **SIDFC**
- Extended ID Filter Configuration **XIDFC**
- Extended ID AND Mask **XIDAM**

Depending on the configuration of the filter element (**SFEC/EFEC**) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag **IR.HPM**
- Set High Priority Message interrupt flag **IR.HPM** and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

#### Rx Buffer

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see **PSR.LEC** respectively **PSR.DLEC**.

#### Rx FIFO

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see **PSR.LEC** respectively **PSR.DLEC**. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in Section 3.4.2.2 have to be considered.

**Note:** When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

#### 3.4.1.1 Range Filter

The filter matches for all received frames with Message IDs in the range defined by **SF1ID/SF2ID** resp. **EF1ID/EF2ID**.

There are two possibilities when range filtering is used together with extended frames:

**EFT** = "00": The Message ID of received frames is ANDed with the Extended ID AND Mask (**XIDAM**) before the range filter is applied

**EFT** = "11": The Extended ID AND Mask (**XIDAM**) is not used for range filtering

#### 3.4.1.2 Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with **SF1ID** = **SF2ID** resp. **EF1ID** = **EF2ID**.

#### 3.4.1.3 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering **SF1ID/EF1ID** is used as Message ID filter, while **SF2ID/EF2ID** is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

### 3.4.1.4 Standard Message ID Filtering

Figure 6 below shows the flow for standard Message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in Section 2.4.5.

Controlled by the Global Filter Configuration **GFC** and the Standard ID Filter Configuration **SIDFC** Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

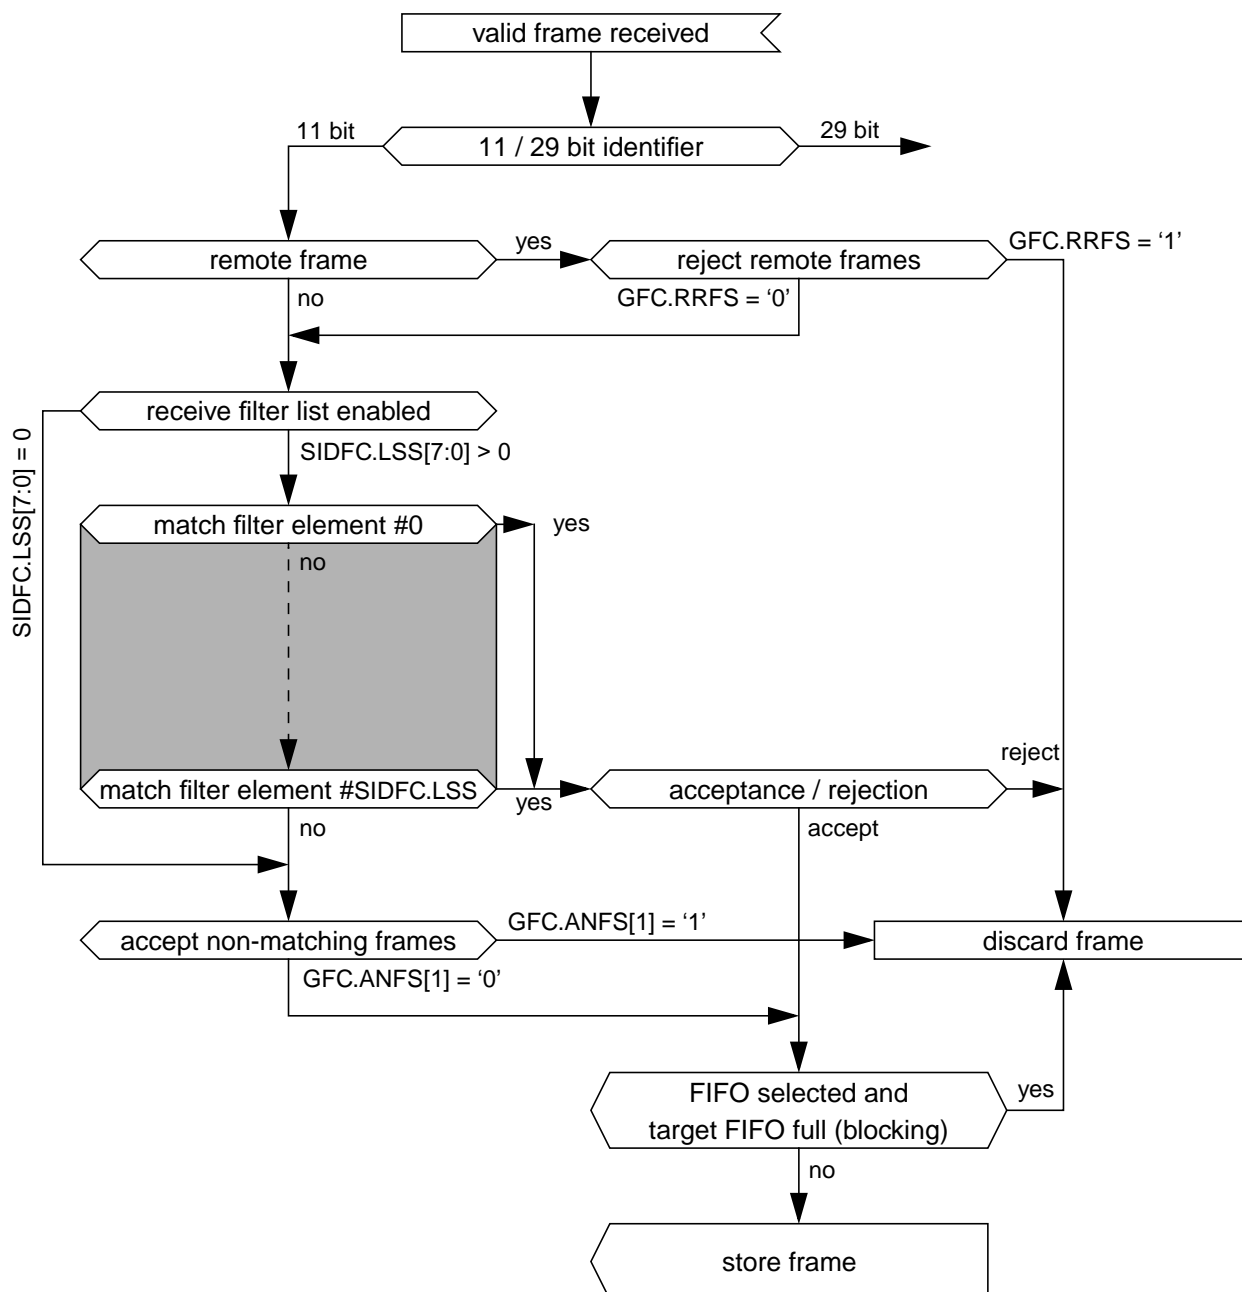

Figure 6 Standard Message ID Filter Path

### 3.4.1.5 Extended Message ID Filtering

Figure 7 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in Section 2.4.6.

Controlled by the Global Filter Configuration **GFC** and the Extended ID Filter Configuration **XIDFC** Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask **XIDAM** is ANDed with the received identifier before the filter list is executed.

Figure 7 Extended Message ID Filter Path

### 3.4.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers **RXF0C** and **RXF1C**.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see Section 3.4.1. The Rx FIFO element is described in Section 2.4.2.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by **RXFnC.FnWM**, interrupt flag **IR.RFnW** is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by **RXFnS.FnF**. In addition interrupt flag **IR.RFnF** is set.

Figure 8 Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index **RXFnS.FnGI** • FIFO Element Size has to be added to the corresponding Rx FIFO start address **RXFnC.FnSA**.

<b>RXESC.RBDS[2:0] RXESC.FnDS[2:0]</b>	<b>Data Field [bytes]</b>	<b>FIFO Element Size [RAM words]</b>
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

Table 55 Rx Buffer / FIFO Element Size

### 3.4.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by **RxFnC.FnOM** = '0'. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (**RxFnS.FnPI** = **RxFnS.FnGI**), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by **RxFnS.FnF** = '1'. In addition interrupt flag **IR.RFnF** is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by **RxFnS.RFnL** = '1'. In addition interrupt flag **IR.RFnL** is set.

### 3.4.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by **RxFnC.FnOM** = '1'.

When an Rx FIFO full condition (**RxFnS.FnPI** = **RxFnS.FnGI**) is signalled by **RxFnS.FnF** = '1', the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. Figure 9 shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

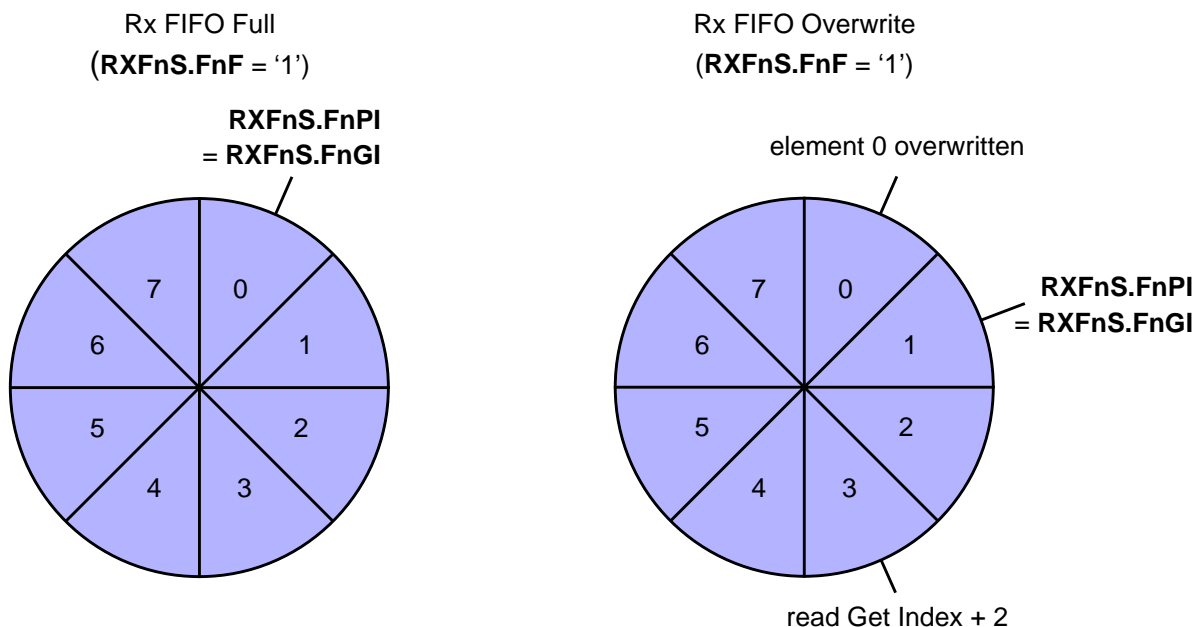

Figure 9 Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index **RxFnA.FnA**. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (**RxFnS.FnF** = '0').

### 3.4.3 Dedicated Rx Buffers

The M\_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via **RXBC.RBSA**.

For each Rx Buffer a Standard or Extended Message ID Filter Element with **SFEC / EFEC** = "111" and **SFID2 / EFID2[10:9]** = "00" has to be configured (see Section 2.4.5 and Section 2.4.6).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag **IR.DRX** (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

<b>Filter Element</b>	<b>SFID1[10:0] EFID1[28:0]</b>	<b>SFID2[10:9] EFID2[10:9]</b>	<b>SFID2[5:0] EFID2[5:0]</b>
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

Table 56 Example Filter Configuration for Rx Buffers

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

#### 3.4.3.1 Rx Buffer Handling

- Reset interrupt flag **IR.DRX**
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

### 3.4.4 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (e.g. #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element (see M\_CAN User's Manual section 2.4.2).

Advantage: Fixed start address for the DMA transfers (relative to **RXBC.RBSA**), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with **SFEC / EFEC** = "111" have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by **SFID2 / EFID2[5:0]**.

After message C has been stored, the DMA request output **m\_can\_dma\_req** is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M\_CAN while **m\_can\_dma\_req** is activated. The behaviour is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets **m\_can\_dma\_ack**. This resets **m\_can\_dma\_req**. Now the M\_CAN is prepared to receive the next set of debug messages.

#### 3.4.4.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages **SFEC / EFEC** has to be programmed to "111". In this case fields **SFID1 / SFID2** and **EFID1 / EFID2** have a different meaning (see Section 2.4.5 and Section 2.4.6). While **SFID2 / EFID2[10:9]** controls the debug message handling state machine, **SFID2 / EFID2[5:0]** controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor **IR.DRX** are set. The reception of debug messages can be monitored via **RXF1S.DMS**.

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

Table 57 Example Filter Configuration for Debug Messages

#### 3.4.4.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signalled via **RXF1S.DMS**.

T0: reset m\_can\_dma\_req output, enable reception of debug messages A, B, and C

T1: reception of debug message A

T2: reception of debug message A

T3: reception of debug message C

T4: reception of debug message B

T5: reception of debug messages A, B

T6: reception of debug message C

T7: DMA transfer completed

T8: reception of debug message A,B,C (message rejected)

Figure 10 Debug Message Handling State Machine

### 3.5 Tx Handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The CAN mode for transmission (Classic CAN or CAN FD) can be configured separately for each Tx Buffer element. The Tx Buffer element is described in Section 2.4.3. Table 58 below describes the possible configurations for frame transmission.

CCCR		Tx Buffer Element		Frame Transmission
BRSE	FDOE	FDF	BRS	
ignored	0	ignored	ignored	ClassicCAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	FD without bit rate switching
1	1	1	1	FD with bit rate switching

Table 58 Possible Configurations for Frame Transmission

**Note:** AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation

The Tx Handler starts a Tx scan of the Message RAM to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register **TXBRP** is updated. **TXBRP** is updated when a transmission finishes, or after the Host has requested a transmission by writing to **TXBAR**, or when the Host has cancelled a pending transmission by writing to **TXBCR**.

When there is a new scan-result, the temporary buffers holding the preloaded first four RAM words of the two messages with the highest Tx priority are updated. The time required for a Tx scan and the preloading depends on the Host clock frequency, on the number of configured Tx Buffers, and on the number of M\_CANs connected the Message RAM.

As the Tx scan of the Message RAM takes some time, the following scenarios are possible:

- Temporary buffer preloaded before ongoing transmission/reception finished:  
Transmission of preloaded Tx message starts at first opportunity
- Preloading of temporary buffer not completed before ongoing transmission/reception finished:  
Tx message cannot be started at first opportunity. In this case another node may start a transmission without having to arbitrate against the transmit message of the M\_CAN. If this other message has lower priority, that may be regarded as an outer priority inversion.

#### 3.5.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If e.g. CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit **CCCR.TXP**. If the bit is set, the M\_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (**CCCR.TXP** = '0').

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

### 3.5.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first. These Tx buffers shall be requested in ascending order with lowest buffer number first. Alternatively, all Tx buffers configured with the same Message ID can be requested simultaneously by a single write access to **TXBAR**.

If the data section has been updated, a transmission is requested by an Add Request via **TXBAR.ARn**. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (see Table 59). Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0...31) • Element Size to the Tx Buffer Start Address **TXBC.TBSA**.

<b>TXESC.TBDS[2:0]</b>	<b>Data Field [bytes]</b>	<b>Element Size [RAM words]</b>
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

Table 59 Tx Buffer / FIFO / Queue Element Size

### 3.5.3 Tx FIFO

Tx FIFO operation is configured by programming **TXBC.TFQM** to '0'. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index **TXFQS.TFGI**. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M\_CAN calculates the Tx FIFO Free Level **TXFQS.TFFL** as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index **TXFQS.TFQPI**. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (**TXFQS.TFQF** = '1') is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a '1' to the **TXBAR** bit related to the Tx Buffer referenced by the Tx FIFO's Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via **TXBAR**. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 59). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index **TXFQS.TFQPI** (0...31) • Element Size to the Tx Buffer Start Address **TXBC.TBSA**.

### 3.5.4 Tx Queue

Tx Queue operation is configured by programming **TXBC.TFQM** to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the transmission order depends on numbers of the buffers where the messages were stored for transmission. As these buffer numbers depend on the then current states of the Put index, a prediction of the transmission order is not possible.

New messages have to be written to the Tx Buffer referenced by the Put Index **TXFQS.TFQPI**. The Put Index always points to that free buffer of the Tx Queue with the lowest buffer number. In case that the Tx Queue is full (**TXFQS.TFQF** = '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register **TXBRP** instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 59). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index **TXFQS.TFQPI** (0...31) • Element Size to the Tx Buffer Start Address **TXBC.TBSA**.

### 3.5.5 Mixed Dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by **TXBC.NDTB**. The number of Tx Buffers assigned to the Tx FIFO is configured by **TXBC.TFQS**. In case **TXBC.TFQS** is programmed to zero, only Dedicated Tx Buffers are used.

Figure 11 Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by **TXFS.TFGI**)
- Buffer with lowest Message ID gets highest priority and is transmitted next

### 3.5.6 Mixed Dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by **TXBC.NDTB**. The number of Tx Queue Buffers is configured by **TXBC.TFQS**. In case **TXBC.TFQS** is programmed to zero, only Dedicated Tx Buffers are used.

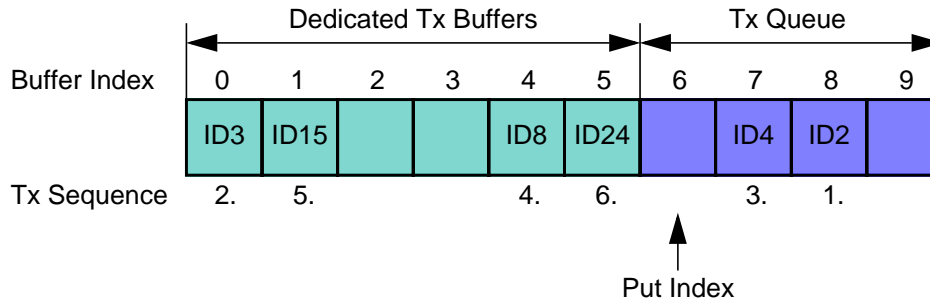

Figure 12 Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

### 3.5.7 Transmit Cancellation

The M\_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a '1' to the corresponding bit position (=number of Tx Buffer) of register **TXBCR**. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of register **TXBCF** to '1'.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding **TXBRP** bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding **TXBTO** and **TXBCF** bits are set. If the transmission was not successful, it is not repeated and only the corresponding **TXBCF** bit is set.

**Note:** In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

### 3.5.8 Tx Event Handling

To support Tx event handling the M\_CAN has implemented a Tx Event FIFO. After the M\_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

Whether an 8-bit Message Marker or a 16-bit Wide Message Marker is used can be configured by **CCCR.WMM**.

**Note:** With **CCCR.WMM = '1'**, internal timestamping is disabled (see Section 2.4.4).

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in Section 2.4.4.

The purpose of the Tx Event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx Buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx Event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx Buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx Buffer before overwriting that Tx Buffer.

When a Tx Event FIFO full condition is signalled by **IR.TEFF**, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag **IR.TEFL** is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by **TXEFC.EFWM**, interrupt flag **IR.TEFW** is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index **TXEFS.EFGI** has to be added to the Tx Event FIFO start address **TXEFC.EFSA**.

## 3.6 FIFO Acknowledge Handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see Section 2.3.29, Section 2.3.33, and Section 2.3.47). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus *one* and thereby updates the FIFO Fill Level. There are two use cases:

When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.

When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M\_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

**Note:** The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M\_CAN does not check for erroneous values.
